Introduction

Epoxy resin prepolymer consists of oligomeric and polymeric diepoxides that are cured to form the finished product by the addition of a fix or hardening agent. The formulation of the prepolymers is vital to controlling the physical properties of the final product. High resolution gel permeation chromatography (GPC) can be used to investigate the oligomeric distributions of epoxy resin prepolymer for formulation and quality control. This application note outlines the analysis of two grades of epoxy resin using Agilent OligoPore columns. Epoxy resins contain strong chromophores therefore, UV detection can be employed.

Epoxy Resin Oligomer Analysis

Figure 1 shows chromatograms of two epoxy resin samples. The first resin contains some high molecular weight material that is excluded on the Agilent OligoPore columns. However, the oligomeric distribution can be seen. The second resin contains no material with a molecular weight greater than about 5,000 g/mol, the exclusion limit of the column. A number of oligomers are resolved. Although the presence of some peaks, with similar retention times, indicates that there are some oligomers common to both samples, the oligomer distributions of the two resins are clearly very different.
**Conditions**

- **Columns**: 2 × Agilent OligoPore, 7.5 × 300 mm (p/n PL1113-6520)
- **Eluent**: THF + 250 ppm BHT
- **Flow rate**: 1.0 mL/min
- **Inj vol**: 100 µL
- **Detector**: UV, 254 nm
- **System**: Agilent PL-GPC 50

**Conclusions**

The relative oligomeric content of two grades of epoxy resin can be compared by high resolution gel permeation chromatography using Agilent OligoPore columns.
