* On arrival, store the Lambda ZAP II vector at –20°C. After thawing, aliquot and store at –20°C. Do not pass through more than two freeze–thaw cycles. For short-term storage, store at 4°C for 1 month.

b Use the SOLR strain for plating excised phagemids and the XL1-Blue MRF’ strain for all other manipulations. For host strain storage conditions, see Bacterial Host Strains.

c Retiter after 1 month. (Take care not to contaminate the Lambda ZAP II vector with the high-titer filamentous helper phage.) Store at –80°C. We recommend the VCSM13 interference-resistant helper phage for single stranded rescue. ExAssist interference-resistant helper phage has α-complementing β-galactosidase sequences which may interfere with sequencing or site-directed mutagenesis where oligonucleotide primers hybridize to β-galactosidase sequences (e.g., M13–20 primer).

STORAGE CONDITIONS

The Lambda ZAP II Vector: –20°C

Helper Phage: –80°C

Bacterial Glycerol Stocks: –80°C

NOTICE TO PURCHASER

The purchase of this vector includes a limited, nonexclusive license to use the vector for the cloning, expression and characterization of genes. This license does not grant rights to (1) use the Lambda ZAP II vector for the reproduction, amplification or modification of the vector; (2) offer the Lambda ZAP II vector or any derivative thereof for resale; (3) distribute or transfer the Lambda ZAP II vector or any derivative thereof to any third party; or (4) incorporate the Lambda ZAP II vector or any derivative thereof in any genomic or cDNA library for resale, distribution or transfer to any third party. No other license, express, implied or by estoppel, is granted. For information concerning the availability of licenses to reproduce and/or modify the Lambda ZAP II vector, please contact Agilent’s Technical Services Department at 1-800-227-9770.
INTRODUCTION

Overview of the Lambda ZAP II Vector System

The Lambda ZAP II system combines the high efficiency of lambda library construction and the convenience of a plasmid system with improved blue–white color selection (see Figure 1). The original Lambda ZAP vector contains the Sam100 mutation, thus limiting the choice of suitable host strains to those containing a supF genotype. Lambda ZAP II, a new variation of the Lambda ZAP vector, no longer contains the Sam100 mutation, therefore, highly efficient growth can be obtained on many non-supF strains, including XL1-Blue MRF’ cells. Use of the XL1-Blue MRF’ host strain with Lambda ZAP II enhances the blue color produced by nonrecombinant phage, thereby improving blue–white color selection.

As with the original Lambda ZAP vector, the Lambda ZAP II vector has six unique cloning sites (Sac I, Not I, Xba I, Spe I, EcoR I, and Xho I) that will accommodate DNA inserts from 0 to 10 kb in length. Clones in the Lambda ZAP II vector can be screened with either DNA probes or antibody probes and allows in vivo rapid excision of the pBluescript phagemid, allowing your insert to be characterized in a plasmid system. The polylinker of the pBluescript phagemid, derived from pUC19, has 21 unique cloning sites flanked by T3 and T7 promoters and a choice of 6 different primer sites for DNA sequencing. The phagemid has the bacteriophage f1 origin of replication, allowing rescue of single-stranded DNA, which can be used for DNA sequencing or site-directed mutagenesis. Unidirectional deletions can be made with exonuclease III and mung bean nuclease by taking advantage of the unique positioning of 5’ and 3’ restriction sites. Transcripts made from the T3 and T7 promoters generate riboprobes useful in Southern and Northern blotting, and the lacZ promoter may be used to drive expression of fusion proteins suitable for Western blot analysis or protein purification.

Lambda ZAP II Vector Map

XL1-Blue MRF’ Bacterial Strain Description

The RecA− *E. coli* host strain XL1-Blue MRF’ is supplied with the Lambda ZAP II vector kit. Because the Lambda ZAP II vector does not require a supF genotype, the amplified library grows very efficiently on the XL1-Blue MRF’ strain. In addition, use of the correct host strain is important when working with the Lambda ZAP II vector as the F’ episome present in the XL1-Blue MRF’ strain serves three purposes.

First, the ΔM15 lacZ gene present on the F’ episome is required for the β-galactosidase-based nonrecombinant selection strategy. When cDNA is present in the polylinker, expression from the lacZ gene is disrupted and white plaques are produced. In contrast, without insert in the polylinker, the amino terminus of β-galactosidase is expressed and nonrecombinants can be scored visually by the presence of blue plaques. To produce an enzymatically active β-galactosidase protein, two domains are required: the α-region expressed by the vector and the ΔM15 lacZ domain expressed by the F’ episome. These two domains fold to form a functional protein, the α-region complementing the missing amino acids resulting from the ΔM15 mutation. Therefore, in order to utilize the nonrecombinant selection strategy, the correct host strain must be used to produce a functional β-galactosidase protein.

Second, the F’ episome expresses the genes forming the F’ pili found on the surface of the bacteria. Without pili formation, filamentous phage (i.e., M13 or f1) infection could not occur. Because the conversion of a recombinant Lambda ZAP II clone to a pBluescript phagemid requires superinfection with a filamentous helper phage, the F’ episome is required for in vivo excision (see In Vivo Excision of the pBluescript Phagemid from the Lambda ZAP II Vector).
Third, the F’ episome contains the lac repressor (lacI gene), which blocks transcription from the lacZ promoter in the absence of the inducer isopropyl-1-thio-β-D-galactopyranoside (IPTG). This repressor is important for controlling expression of fusion proteins which may be toxic to the E. coli. Because the presence of the lacI repressor in the E. coli host strain can potentially increase the representation or completeness of the library, XL1-Blue MRF’ is useful for screening the amplified library.

Note  The strains used for the Lambda gt11 vector (i.e., Y1088, Y1089, and Y1090) are not suitable for use with the Lambda ZAP II vector because these strains contain the plasmid pMC9, a pBR322 derivative, which contains many of the same sequences as those found in the phagemid portion of the Lambda ZAP II vector. Using these strains with the Lambda ZAP II vector could result in recombination between the homologous sequences.

Recommended Media

</tr>
</tbody>
</table>

\(^a\) See Preparation of Media and Reagents.  
\(^b\) LB broth with 0.2% (w/v) maltose and 10 mM MgSO\(_4\).  
\(^c\) Maltose and magnesium supplements are required for optimal lambda phage receptor expression on the surface of the XL1-Blue MRF’ host cell. The media supplements are not required for helper phage infection, but are included in both protocols for simplified media preparation.

Establishing an Agar Plate Bacterial Stock

The bacterial host strains are shipped as bacterial glycerol stocks. On arrival, prepare the following plates from the bacterial glycerol stocks.

Note  The host strains may thaw during shipment. The vials should be stored immediately at ~20°C or ~80°C, but most strains remain viable longer if stored at ~80°C. It is best to avoid repeated thawing of the host strains in order to maintain extended viability.

1. Revive the stored cells by scraping off splinters of solid ice with a sterile wire loop.

2. Streak the splinters onto an LB agar plate containing the appropriate antibiotic (see Recommended Media), if one is necessary.

3. Incubate the plate overnight at 37°C.

4. Seal the plate with Parafilm® laboratory film and store the plate at 4°C for up to 1 week.

5. Restreak the cells onto a fresh plate every week.
Preparing a –80°C Bacterial Glycerol Stock

1. In a sterile 50-ml conical tube, inoculate 10 ml of LB broth with the appropriate antibiotic (see Recommended Media) with one colony from the plate. Grow the cells to late log phase.

2. Add 4.5 ml of a sterile glycerol-liquid medium solution (prepared by mixing 5 ml of glycerol + 5 ml of the appropriate medium) to the bacterial culture from step 1. Mix well.

3. Aliquot into sterile centrifuge tubes (1 ml/tube).

This preparation may be stored at –20°C for 1–2 years or at –80°C for more than 2 years.

Growth of Cells for Plating Phage

Bacterial cultures for plating phage should be started from a fresh plate using a single colony and should be grown overnight with vigorous shaking at 30°C in 50 ml of LB broth supplemented with 0.2% (w/v) maltose and 10 mM MgSO₄. (Do not use tetracycline in the presence of magnesium.) The lower temperature ensures that the cells will not overgrow. The cells should be spun at 1000 × g for 10 minutes then gently resuspended in 10 ml of 10 mM MgSO₄. Before use, dilute cells to an OD₆₀₀ of 0.5 with 10 mM MgSO₄. Bacterial cells prepared in this manner can be used for all phage manipulations described within the manual. Highest efficiencies are obtained from freshly prepared cells.

Determining Background by Color Selection with IPTG and X-gal

The color selection by α-complementation with the Lambda ZAP II vector requires higher amounts of IPTG and X-gal for generation of the blue color. Transcription and translation of the fusion protein are normal, but the large poly linker present within the pBluescript phagemid, which is present in the Lambda ZAP II vector, is partly responsible for the reduced activity of the β-galactosidase protein—not the promoter. As would be expected, the copy number of the Lambda ZAP II vector is much less per cell than the copy number of pBluescript phagemids. However, it is important to note that the color assay is used only for determining the ratio of recombinants to nonrecombinants within a newly constructed library and is not used for any other manipulations.
HELPER PHAGE

Two different helper phages are provided with the Lambda ZAP II vector kit: (1) the ExAssist interference-resistant helper phage with SOLR strain and (2) the VCSM13 helper phage. The ExAssist interference-resistant helper phage with SOLR strain is designed to allow efficient in vivo excision of the pBluescript phagemid from the Lambda ZAP II vector while preventing the problems that can be associated with helper phage co-infection. The ExAssist helper phage contains an amber mutation that prevents replication of the phage genome in a nonsuppressing E. coli strain (e.g., SOLR cells). Only the excised phagemid can replicate in the host, removing the possibility of co-infection from the ExAssist helper phage. The ExAssist helper phage cannot be used for single-stranded rescue due to its inability to replicate in the SOLR strain. The other helper phage, VCSM13 helper phage, is recommended for single-stranded rescue procedures from the excised pBluescript phagemids (see Appendix: Recovery of Single-Stranded DNA from Cells Containing pBluescript Phagemids).

Storing the Helper Phage

The ExAssist helper phage and the VCSM13 helper phage are supplied in 7% dimethylsulfoxide (DMSO) and should be stored at –80°C. The helper phage may be stored for short periods of time at –20°C or 4°C. It is important to titer the helper phage prior to each use. Expect titers of approximately 10^10 pfu/ml for the ExAssist helper phage or 10^11 pfu/ml for the VCSM13 helper phage. If the titer drops over time, prepare a fresh high-titer stock of the helper phage as outlined in Amplifying the Helper Phage.

Titering the Helper Phage

1. Transfer a colony of XL1-Blue MRF’ cells into 10 ml of LB broth with supplements in a 50-ml conical tube. Incubate the conical tube with shaking at 37°C until growth reaches an OD<sub>600</sub> of 1.0.

2. Dilute the phage (10^-4–10^-7) in SM buffer (See Preparation of Media and Reagents) and combine 1 µl of each dilution with 200 µl of XL1-Blue MRF’ cells (OD<sub>600</sub> = 1.0).

3. Incubate the helper phage and the XL1-Blue MRF’ cells for 15 minutes at 37°C to allow the phage to attach to the cells.

4. Add 3 ml of NZY top agar, melted and cooled to ~48°C, and plate immediately onto dry, prewarmed NZY agar plates. Allow the plates to set for 10 minutes.
Invert the plates and incubate overnight at 37°C.

**Note** *ExAssist and VCSM13 plaques will have a cloudier appearance than lambda phage plaques.*

To determine the titer [in plaque-forming units per milliliter (pfu/ml)], use the following formula:

\[
\text{Number of plaques (pfu) \times \text{dilution factor}} \div \text{Volume plated (\mu{l})} \times 1000 \mu{l} / \text{ml}
\]

where the volume plated (in microliters) refers to the volume of the helper phage solution added to the cells.

**Amplifying the Helper Phage**

1. Transfer a colony of XL1-Blue MRF’ cells into 10 ml of LB broth with supplements in a 50-ml conical tube. Incubate the conical tube with shaking at 37°C until growth reaches an OD_{600} of 0.3.

   **Note** *An OD_{600} of 0.3 corresponds to 2.5 \times 10^8 cells/ml.*

2. Add the helper phage at a multiplicity of infection (MOI) of 20:1 (phage-to-cells ratio).

3. Incubate the conical tube at 37°C for 15 minutes to allow the phage to attach to the cells.

4. Incubate the conical tube with shaking at 37°C for 8 hours.

   **Note** *When amplifying VCSM13 helper phage, add kanamycin to a final concentration of 25 \mu{g/ml} after 30 minutes of growth.*

5. Heat the conical tube at 65°C for 15 minutes.

6. Spin down the cell debris and transfer the supernatant to a fresh conical tube.

7. The titer of the supernatant should be between \(7.5 \times 10^{10}\) and \(1.0 \times 10^{12}\) pfu/ml for ExAssist helper phage or between \(1.0 \times 10^{11}\) and \(1.0 \times 10^{12}\) pfu/ml for VCSM13 helper phage.

   **Note** *ExAssist and VCSM13 plaques will have a cloudier appearance than lambda phage plaques.*

8. Add dimethylsulfoxide (DMSO) to a final concentration of 7% (v/v) and store at –80°C.

9. For further details about helper phage titering or amplification, please see *Titering the Helper Phage* or Reference 4.
PREPARING THE LAMBDA ZAP II VECTOR

The Lambda ZAP II vector is shipped in a 10 mM Tris-HCl (pH 7.0) and 0.1 mM EDTA buffer and can be stored up to 1 month at 4°C. For long-term storage, freeze at –20°C in aliquots. However, do not put the samples through multiple freeze–thaw cycles.

Note Due to the high molecular weight of the lambda vector, the contents may be very viscous. It is important to microcentrifuge the contents of the lambda vector tube briefly at 11,000 × g, then gently mix the solution by stirring with a yellow pipet tip prior to pipetting.

Preparing for Digestion

The cos ends should be ligated prior to digestion when the vector will be filled in. The cos ligation procedure is not necessary when the fill-in procedure is not used.

Ligating the cos Sites

Note In all ligations, it is important to limit the final glycerol content to less than 5% (v/v).

10 µg of Lambda ZAP II vector DNA
2 µl of 10× ligase buffer (see Preparation of Media and Reagents)
2 µl of 10 mM rATP (pH 7.5)
X µl of T4 DNA ligase (8 U) [Keep the final glycerol content below 5% (v/v).]
X µl of water for a final volume of 20 µl

1. Incubate overnight at 4°C.
2. Heat for 15 minutes at 68°C to inactivate the ligase.
3. Cool for 15 minutes at room temperature.
**Digestion**

The lambda DNA should be digested for the minimum time and amount of enzyme to obtain a complete digestion. Overdigestion with the restriction enzyme will lower efficiency, while underdigestion will result in increased background.

Perform a pilot digestion to test a range of enzyme digestion incubation times. Package 0.4 µg from each time point, also packaging 0.4 µg of undigested Lambda ZAP II vector as a control. (Plate a dilution of the undigested Lambda ZAP II vector packaging mix in order to count a manageable number of plaques.) Choose the time point that gives less than 0.1% of the plating efficiency of uncut Lambda ZAP II vector.

1. Digest 2.5 µg of Lambda ZAP II vector with 2–5 U of enzyme/µg of DNA in a final volume of 25 µl.

2. Remove 0.5 µg (5 µl) at each time point, stopping the reaction by adding the aliquot to 0.5 µl of 10× STE buffer [100 mM Tris-HCl (pH 8.0), 1 M NaCl and 10 mM EDTA (pH 8.0)].

Suggested time points are as follows:

1 hour, 45 minutes
2 hours, 0 minutes
2 hours, 15 minutes
2 hours, 30 minutes
2 hours, 45 minutes

3. Package 0.4 µg (4 µl) and plate according to the instructions in *Plating for Blue-White Color Selection.*

**Note** Incomplete digestion by Not I has been reported. This may be correlated with the high viscosity of concentrated lambda phage DNA after cos ligation. It may be necessary to reduce the concentration of the DNA to approximately 0.1 µg/µl when digesting with this enzyme.
4. After determining the ideal time point:
   a. Digest 5 µg of Lambda ZAP II vector in a final volume of 50 µl.
   c. Chloroform extract once with an equal volume.
   d. Adjust the aqueous phase to 0.3 M NaOAc.
   e. Ethanol precipitate with 2.5 volumes of 100% (v/v) cold ethanol.
   f. Wash the pellet once with 70% (v/v) ethanol.
   g. Resuspend the DNA in a 10 mM Tris (pH 7.4) and 1 mM EDTA solution.

**Partial Fill-In Technique**

DNA with *Hind* III- or *Bam*H I-compatible ends can be cloned into the Lambda ZAP II vector by using the *Spe*I–*Hind* III or *Xho*I–*Bam*HI partial fill-in technique.

Following *cos* ligation:

1. Digest the Lambda ZAP II vector DNA to completion with the appropriate enzyme according to the above procedure. DO NOT OVER DIGEST.

2. Digest the insert partially or completely with the appropriate enzyme as desired.

3. Fill in the two required nucleotides for the vector and the two required nucleotides for the insert.

To fill in 10 µg of Lambda ZAP II vector DNA, add:

- 1 µl of 10 mM dTTP
- 1 µl of 10 mM dCTP
- 1 µl of 10 × fill-in buffer
- 1 U of Klenow
- Total 10 µl

To fill in 10 µg of insert, add:

- 2 µl of 10 mM dATP
- 2 µl of 10 mM dGTP
- 2 µl of 10× fill-in buffer
- 2 U Klenow
- Total 20 µl

Incubate for 30 minutes at room temperature, then place at 65°C for 15 minutes.

§ See Preparation of Media and Reagents.

5. Chloroform extract once with an equal volume.

6. Adjust the aqueous phase to 0.3 M NaOAc.

7. Ethanol precipitate with 2.5 volumes of 100% (v/v) cold ethanol.

8. Wash the pellet once with 70% (v/v) ethanol.

Calf Intestinal Alkaline Phosphatase Treatment

Phosphatase the vector that has not been filled in prior to ligation. A procedure is outlined in Sambrook et al. The calf intestinal alkaline phosphatase (CIAP) reaction can be carried out in the digestion buffer with the addition of 10× CIAP buffer (see Preparation of Media and Reagents). If using universal buffer, CIAP can be performed without the addition of CIAP buffer.

LIGATING THE INSERT

Notes When preparing the vector arms, it may be useful to prepare a test insert to confirm the quality of the lambda arms.

In all ligations, it is important to limit the final glycerol content to less than 5% (v/v).

Add the following components in order:

$X$ µl of Lambda ZAP II prepared arms (1 µg)

$X$ µl of insert (0.4 µg)

0.5 µl of 10× ligase buffer

0.5 µl of 10 mM rATP (pH 7.5)

$X$ µl of water for a final volume of 5 µl

$X$ µl of T4 DNA ligase (2 Weiss U)

Incubate at 12–14°C overnight or at 4°C for 2 days.

When ligating the insert, use a volume up to 2.5 µl. Use an equal molar ratio (or less to prevent multiple inserts) of the insert. The Lambda ZAP II vector can accommodate inserts ranging from 0 to 10 kb. The Lambda ZAP II vector is ~41,000 bp in length. If ligating a 4,000-bp insert to the vector, use 0.1 µg of insert for every 1 µg of vector. If the insert used is free from contaminants and contains a high percentage of ligatable ends, expect about $2 \times 10^6$–$1.5 \times 10^7$ recombinant plaques when using high-efficiency packaging extracts, such as Gigapack III Plus or Gigapack III Gold packaging extracts (Catalog #200201 and #200204, respectively).
**DETERMINING BACKGROUND BY BLUE-WHITE COLOR SELECTION**

A background test can be completed by plating several hundred plaques on a plate (see Determining Background by Color Selection with IPTG and X-gal). Add 15 μl of 0.5 M IPTG (in water) and 50 μl of 250 mg/ml X-gal [in dimethylformamide (DMF)] to 2–3 ml of NZY top agar, melted and cooled to ~48°C. The higher concentrations of IPTG and X-gal used in the plating often result in the formation of a precipitate, which disappears after incubation. Add IPTG and X-gal to the NZY top agar separately, with mixing in between additions, to minimize the formation of this precipitate. Plate immediately on NZY agar plates. Plaques are visible after incubation for 12 hours at 37°C, although color detection requires overnight incubation. Background plaques are blue, while recombinant plaques are white.

1. To plate the packaged ligation product, mix the following components:

   - 1 μl of the final packaged reaction
   - 200 μl of XL1-Blue MRF’ cells at an OD600 of 0.5

   and

   - 1 μl of a 1:10 dilution of the final packaged reaction
   - 200 μl of XL1-Blue MRF’ cells at an OD600 of 0.5

   **Note** Use of any other cell line may result in a dramatically reduced titer. XL1-Blue MRF’ is a RecA– McrA– and McrCB– Mrr– strain and does not restrict methylated DNA.5–8

2. Incubate the phage and the bacteria at 37°C for 15 minutes to allow the phage to attach to the cells.

3. Add the following components:

   - 2–3 ml of NZY top agar (melted and cooled to ~48°C)
   - 15 μl of 0.5 M IPTG (in water)
   - 50 μl of X-gal [250 mg/ml (in DMF)]

4. Plate immediately onto dry, prewarmed NZY agar plates and allow the plates to set for 10 minutes. Invert the plates and incubate at 37°C.

5. Plaques should be visible after 12 hours, although color detection requires overnight incubation. Background plaques are blue and should be <1 × 10^5 pfu/μg of arms, while recombinant plaques will be white (clear) and should be 10- to 100-fold above the background.
TITERING THE LIBRARY

Preparing the Host Bacteria

1. Streak the XL1-Blue MRF’ cells onto an LB-tetracycline agar plate. Incubate the plate overnight at 37°C.

   **Note**  Do not add antibiotic to the medium in the following step. The antibiotic will bind to the bacterial cell wall and will inhibit the ability of the phage to infect the cell.

2. Prepare a 50-ml culture of XL1-Blue MRF’ cells in LB broth with supplements.

3. Incubate with shaking at 37°C for 4–6 hours (do not grow past an OD_{600} of 1.0). Alternatively, grow overnight at 30°C, shaking at 200 rpm.

   **Note**  The lower temperature keeps the bacteria from overgrowing, thus reducing the number of nonviable cells. Phage can adhere to nonviable cells resulting in a decreased titer.

4. Pellet the bacteria at 1000 × g for 10 minutes.

5. Gently resuspend the cell pellet in 25 ml sterile 10 mM MgSO_{4}.

   **Note**  For later use, store the cells at 4°C overnight in 10 mM MgSO_{4}.

Titering Protocol

1. Dilute the XL1-Blue MRF’ cells (from step 5 of Preparing the Host Bacteria) to an OD_{600} of 0.5 with sterile 10 mM MgSO_{4}.

   **Note**  The bacteria should be used immediately following dilution.

2. To determine the titer of the packaged ligation product, mix the following components:

   1 μl of the final packaged reaction
   200 μl of XL1-Blue MRF’ cells at an OD_{600} of 0.5

   and

   1 μl of a 1:10 dilution of the final packaged reaction
   200 μl of XL1-Blue MRF’ cells at an OD_{600} of 0.5

3. Incubate the phage and the bacteria at 37°C for 15 minutes to allow the phage to attach to the cells.
4. Add 3 ml of NZY top agar, melted and cooled to ~48°C, and plate immediately onto dry, prewarmed NZY agar plates. Allow the plates to set for 10 minutes. Invert the plates and incubate at 37°C.

5. Plaques should be visible after 12 hours. Count the plaques and determine the titer in plaque-forming units per milliliter (pfu/ml).

Note: Primary libraries can be unstable; therefore, amplification of the libraries is recommended immediately.

AMPLIFYING THE LIBRARY

It is usually desirable to amplify libraries prepared in lambda vectors to make a large, stable quantity of a high-titer stock of the library. However, more than one round of amplification is not recommended, since slower growing clones may be significantly underrepresented.

The following protocol is recommended for amplifying the Lambda ZAP II library:

**Day 1**

1. Grow a 50-ml overnight culture of XL1-Blue MRF’ cells in LB broth with supplements at 30°C with shaking.

**Day 2**

2. Gently spin down the XL1-Blue MRF’ cells (1000 × g). Resuspend the cell pellet in 25 ml of 10 mM MgSO₄. Measure the OD₆₀₀ of the cell suspension, then dilute the cells to an OD₆₀₀ of 0.5 in 10 mM MgSO₄.

3. Combine aliquots of the packaged mixture or library suspension containing ~5 × 10⁴ pfu of bacteriophage with 600 µl of XL1-Blue MRF’ cells at an OD₆₀₀ of 0.5 in 14-ml BD Falcon® polypropylene round-bottom tubes. To amplify 1 × 10⁶ plaques, use a total of 20 aliquots (each aliquot contains 5 × 10⁴ plaques/150-mm plate).

Note: Do not add more than 300 µl of phage/600 µl of cells.

4. Incubate the tubes containing the phage and host cells for 15 minutes at 37°C to allow the phage to attach to the cells.

5. Mix 6.5 ml of NZY top agar, melted and cooled to ~48°C, with each aliquot of infected bacteria and spread evenly onto a freshly poured 150-mm NZY agar plate. Allow the plates to set for 10 minutes.

6. Invert the plates and incubate at 37°C for 6–8 hours. Do not allow the plaques to get larger than 1–2 mm. On completion, the plaques should be touching.
7. Overlay the plates with ~8–10 ml of SM buffer. Store the plates at 4°C overnight (with gentle rocking if possible). This allows the phage to diffuse into the SM buffer.

**Day 3**

8. Recover the bacteriophage suspension from each plate and pool it into a sterile polypropylene container. Rinse the plates with an additional 2 ml of SM buffer and pool. Add chloroform to a 5% (v/v) final concentration. Mix well and incubate for 15 minutes at room temperature.

9. Remove the cell debris by centrifugation for 10 minutes at 500 × g.

10. Recover the supernatant and transfer it to a sterile polypropylene container. If the supernatant appears cloudy or has a high amount of cell debris, repeat steps 8 and 9. If the supernatant is clear, add chloroform to a 0.3% (v/v) final concentration and store at 4°C. Store aliquots of the amplified library in 7% (v/v) DMSO at –80°C.

11. Check the titer of the amplified library using host cells and serial dilutions of the library. (Assume ~10⁹–10¹¹ pfu/ml.)

**Note**  *Briefly spin the lambda phage stock to ensure that the chloroform is separated completely before removing the aliquot for titering.*
PERFORMING PLAQUE LIFTS

1. Titer the amplified mixture or library suspension to determine the concentration using XL1-Blue MRF’ cells.

2. Combine the equivalent of $5 \times 10^4$ pfu/plate and 600 µl of freshly prepared XL1-Blue MRF’ cells at an OD$_{600}$ of 0.5.

3. Incubate the bacteria and phage mixture at 37°C for 15 minutes to allow the phage to attach to the cells.

4. Add 6.5 ml of NZY top agar (~48°C) to the bacteria and phage mixture.

5. Quickly pour the plating culture onto a dry, prewarmed 150-mm NZY agar plate, which is at least 2 days old. Carefully swirl the plate to distribute the cells evenly. Allow the plates to set for 10 minutes. (Use 20 plates to screen 1 × 10⁶ pfu.)

6. Invert the plates and incubate at 37°C for ~8 hours.

7. Chill the plates for 2 hours at 4°C to prevent the top agar from sticking to the nitrocellulose membrane.

   **Note** Use forceps and wear gloves for the following steps.

8. Place a nitrocellulose membrane onto each NZY agar plate for 2 minutes to allow the transfer of the phage particles to the membrane. Use a needle to prick through the membrane and agar for orientation. (If desired, waterproof ink in a syringe needle may be used.)

**Notes** If making duplicate nitrocellulose membranes, allow the second membrane to transfer for ~4 minutes.

Pyrex® dishes are convenient for the following steps. All solutions should be at room temperature.

a. Denature the nitrocellulose-bound DNA after lifting by submerging the membrane in a 1.5 M NaCl and 0.5 M NaOH denaturation solution for 2 minutes.

   **Note** If using charged nylon, wash with gloved fingertips to remove the excess top agar.

b. Neutralize the nitrocellulose membrane for 5 minutes by submerging the membrane in a 1.5 M NaCl and 0.5 M Tris-HCl (pH 8.0) neutralization solution.

c. Rinse the nitrocellulose membrane for no more than 30 seconds by submerging the membrane in a 0.2 M Tris-HCl (pH 7.5) and 2× SSC buffer solution (see Preparation of Media and Reagents).
9. Blot briefly on a Whatman® 3MM paper.

10. Crosslink the DNA to the membranes using the autocrosslink setting on the Stratalinker UV crosslinker* (120,000 μJ of UV energy) for ~30 seconds. Alternatively, oven bake at 80°C for ~1.5–2 hours.

11. Store the stock agar plates of the transfers at 4°C to use after screening.

**HYBRIDIZING AND SCREENING**

Following the preparation of the membranes for hybridization, perform prehybridization, probe preparation, hybridization, and washes for either oligonucleotide probes or double-stranded probes and then expose the membranes to film as outlined in standard methodology texts. When using the Lambda ZAP II vector, perform in vivo excision on the isolates to obtain the insert-containing pBluescript phagemid, or after an isolate is obtained, refer to Reference 4 for suggested phage miniprep and maxiprep procedures.

**ANTIBODY SCREENING PROTOCOL**

A complete instruction manual for immunoscreening is supplied with the Agilent picoBlue immunoscreening kit. This kit is available with goat anti-rabbit antibodies or goat anti-mouse antibodies [Catalog #200371 (goat anti-rabbit) and #200372 (goat anti-mouse)].

* Available from Agilent, Catalog #400071 (1800) and #400075 (2400).
In Vivo Excision of the pBluescript Phagemid from the Lambda ZAP II Vector

The Lambda ZAP II vector is designed to allow simple, efficient in vivo excision and recircularization of any cloned insert contained within the lambda vector to form a phagemid containing the cloned insert. This in vivo excision depends on the placement of the DNA sequences within the lambda phage genome and on the presence of a variety of proteins, including f1 bacteriophage-derived proteins. The f1 phage proteins recognize a region of DNA normally serving as the f1 bacteriophage origin of replication. This origin of replication can be divided into two overlying parts: (1) the site of initiation and (2) the site of termination for DNA synthesis.10 These two regions are subcloned separately into the Lambda ZAP II vector. The lambda phage (target) is made accessible to the f1-derived proteins by simultaneously infecting a strain of E. coli with both the lambda vector and the f1 bacteriophage.

Inside E. coli, the "helper" proteins (i.e., proteins from f1 or M13 phage) recognize the initiator DNA that is within the lambda vector. One of these proteins then nicks one of the two DNA strands. At the site of this nick, new DNA synthesis begins and duplicates whatever DNA exists in the lambda vector "downstream" (3’) of the nicking site. DNA synthesis of a new single strand of DNA continues through the cloned insert until a termination signal, positioned 3’ of the initiator signal, is encountered within the constructed lambda vector. The single-stranded DNA molecule is circularized by the gene II product from the f1 phage, forming a circular DNA molecule containing the DNA between the initiator and terminator. In the case of the Lambda ZAP II vector, this includes all sequences of the pBluescript SK(−) phagemid and the insert, if one is present. This conversion is the "subcloning" step, since all sequences associated with normal lambda vectors are positioned outside of the initiator and terminator signals and are not contained within the circularized DNA. In addition, the circularizing of the DNA automatically recreates a functional f1 origin as found in f1 bacteriophage or phagemids.
In Vivo Excision Protocols Using ExAssist Helper Phage with SOLR Strain

The ExAssist helper phage with SOLR strain is designed to allow efficient excision of the pBluescript phagemid from the Lambda ZAP II vector, while eliminating problems associated with helper phage co-infection. The ExAssist helper phage contains an amber mutation that prevents replication of the phage genome in a nonsuppressing E. coli strain such as SOLR cells. This allows only the excised phagemid to replicate in the host, removing the possibility of co-infection from the ExAssist helper phage. Since the ExAssist helper phage cannot replicate in the SOLR strain, single-stranded rescue cannot be performed in this strain using this helper phage.

Mass excision can be used to generate subtraction libraries and subtracted DNA probes.

Single-Clone Excision Protocol

Day 1

1. Core the plaque of interest from the agar plate and transfer the plaque to a sterile microcentrifuge tube containing 500 µl of SM buffer and 20 µl of chloroform. Vortex the microcentrifuge tube to release the phage particles into the SM buffer. Incubate the microcentrifuge tube for 1–2 hours at room temperature or overnight at 4°C. (This phage stock is stable for up to 6 months at 4°C.)

2. Grow separate 50-ml overnight cultures of XL1-Blue MRF’ and SOLR cells in LB broth with supplements at 30°C.

Day 2

3. Gently spin down the XL1-Blue MRF’ and SOLR cells (1000 × g). Resuspend each of the cell pellets in 25 ml of 10 mM MgSO₄. Measure the OD₆₀₀ of the cell suspensions, then adjust the concentration of the cells to an OD₆₀₀ of 1.0 (8 × 10⁸ cells/ml) in 10 mM MgSO₄.

4. Combine the following components in a BD Falcon polypropylene tube:

   200 µl of XL1-Blue MRF’ cells at an OD₆₀₀ of 1.0
   250 µl of phage stock (containing >1 × 10⁵ phage particles)
   1 µl of the ExAssist helper phage (>1 × 10⁶ pfu/µl)

   **Note** Briefly spin the lambda phage stock to ensure that the chloroform is separated completely before removing the aliquot used in the excision reaction.

5. Incubate the BD Falcon polypropylene tube at 37°C for 15 minutes to allow the phage to attach to the cells.
6. Add 3 ml of LB broth with supplements and incubate the BD Falcon polypolypropylene tube for 2.5–3 hours at 37°C with shaking. Because clonal representation is not relevant, single-clone excision reactions can be safely performed overnight.

**Note** The turbidity of the media is not indicative of the success of the excision.

7. Heat the BD Falcon polypolypropylene tube at 65–70°C for 20 minutes to lyse the lambda phage particles and the cells. Spin the tube at $1000 \times g$ for 15 minutes to pellet the cell debris.

8. Decant the supernatant into a sterile BD Falcon polypolypropylene tube. This stock contains the excised pBluescript phagemid packaged as filamentous phage particles. (This stock may be stored at 4°C for 1–2 months.)

9. To plate the excised phagemids, add 200 μl of freshly grown SOLR cells from step 3 (OD$_{600} = 1.0$) to two 1.5-ml microcentrifuge tubes. Add 100 μl of the phage supernatant (from step 8 above) to one microcentrifuge tube and 10 μl of the phage supernatant to the other microcentrifuge tube.

10. Incubate the microcentrifuge tubes at 37°C for 15 minutes.

11. Plate 200 μl of the cell mixture from each microcentrifuge tube on LB-ampicillin agar plates (100 μg/ml) and incubate the plates overnight at 37°C.

Due to the high-efficiency of the excision process, it may be necessary to titrate the supernatant to achieve single-colony isolation.

Colonies appearing on the plate contain the pBluescript double-stranded phagemid with the cloned DNA insert. Helper phage will not grow, since helper phage is unable to replicate in the Su- (nonsuppressing) SOLR strain and does not contain ampicillin-resistance genes. SOLR cells are also resistant to lambda phage infection, thus preventing lambda phage contamination after excision.

To maintain the pBluescript phagemid, streak the colony on a new LB-ampicillin agar plate. For long-term storage, prepare a bacterial glycerol stock and store at –80°C.

VCSM13 helper phage is recommended for the single-stranded rescue procedure. The single-stranded rescue procedure can be found in Appendix: Recovery Of Single-Stranded DNA From Cells Containing pBluescript Phagemids.
Mass Excision Protocol

Day 1

1. Grow separate 50-ml overnight cultures of XL1-Blue MRF’ and SOLR cells in LB broth with supplements at 30°C.

Day 2

2. Gently spin down the XL1-Blue MRF’ and SOLR cells (1000 × g). Resuspend each of the cell pellets in 25 ml of 10 mM MgSO₄. Measure the OD₆₀₀ of the cell suspensions, then adjust the concentration of the cells to an OD₆₀₀ of 1.0 (8 × 10⁸ cells/ml) in 10 mM MgSO₄.

3. In a 50-ml conical tube, combine a portion of the amplified lambda bacteriophage library with XL1-Blue MRF’ cells at a MOI of 1:10 lambda phage-to-cell ratio. Excise 10- to 100-fold more lambda phage than the size of the primary library to ensure statistical representation of the excised clones. Add ExAssist helper phage at a 10:1 helper phage-to-cells ratio to ensure that every cell is co-infected with lambda phage and helper phage.

For example, use

- 10⁷ pfu of the lambda phage (i.e., 10- to 100-fold above the primary library size)
- 10⁸ XL1-Blue MRF’ cells (1:10 lambda phage-to-cell ratio, noting that an OD₆₀₀ of 1.0 corresponds to 8 × 10⁸ cells/ml)
- 10⁹ pfu of ExAssist helper phage (10:1 helper phage-to-cells ratio)

Note Briefly spin the lambda phage stock to ensure that the chloroform is separated completely before removing the aliquot used in the excision reaction.

4. Incubate the conical tube at 37°C for 15 minutes to allow the phage to attach to the cells.

5. Add 20 ml of LB broth with supplements and incubate the conical tube for 2.5–3 hours at 37°C with shaking.

Notes Incubation times for mass excision in excess of 3 hours may alter the clonal representation.

The turbidity of the media is not indicative of the success of the excision.

6. Heat the conical tube at 65–70°C for 20 minutes to lyse the lambda phage particles and the cells.

7. Spin the conical tube at 1000 × g for 10 minutes to pellet the cell debris and then decant the supernatant into a sterile conical tube.
8. To titer the excised phagemids, combine 1 μl of this supernatant with 200 μl of SOLR cells from step 2 in a 1.5-ml microcentrifuge tube.

9. Incubate the microcentrifuge tube at 37°C for 15 minutes.

10. Plate 100 μl of the cell mixture onto LB–ampicillin agar plates (100 μg/ml) and incubate the plates overnight at 37°C.

   **Note**  *It may be necessary to further dilute the cell mixture to achieve single-colony isolation.*

At this stage, colonies may be selected for plasmid preps, or the cell mixture may be plated directly onto filters for colony screening.
APPENDIX: RECOVERY OF SINGLE-STRANDED DNA FROM CELLS CONTAINING pBLUESCRIPT PHAGEMIDS

pBluescript is a phagemid that can be secreted as single-stranded DNA in the presence of M13 helper phage. These phagemids contain the intergenic (IG) region of a filamentous f1 phage. This region encodes all of the cis-acting functions of the phage required for packaging and replication. In E. coli with the F' phenotype (containing an F' episome), pBluescript phagemids will be secreted as single-stranded f1 "packaged" phage when the bacteria has been infected by a helper phage. Since these filamentous helper phages (M13, f1) will not infect E. coli without an F' episome coding for pili, **it is essential to use XL1-Blue MRF' or a similar strain containing the F' episome.**

Agilent offers helper phages that preferentially package pBluescript phagemids. Typically, 30–50 pBluescript molecules are packaged/helper phage DNA molecule. pBluescript phagemids are offered with the IG region in either of two orientations: pBluescript (+) is replicated such that the sense strand of the β-galactosidase gene is secreted within the phage particles; pBluescript (–) is replicated such that the antisense strand of the β-galactosidase gene is secreted in the phage particles.

Yields of single-stranded (ss)DNA depend on the specific insert sequence. For most inserts, over 1 µg of ssDNA can be obtained from a 1.5-ml miniprep if grown in XL1-Blue MRF'. A faint single-strand helper phage band may appear on a gel at ~6 kb for VCSM13. This DNA mixture can be sequenced with primers that are specific for pBluescript and do not hybridize to the helper phage genome.

Site-specific mutagenesis is also possible using standard techniques. The advantages of using pBluescript phagemids for either purpose are as follows: (1) pBluescript phagemids do not replicate via the M13 cycle, lessening the tendency to delete DNA inserts, therefore it is unlikely that even 10-kb inserts will be deleted. (2) "Packaging" of pBluescript phagemids containing inserts is efficient since the pBluescript vector is significantly smaller than wild-type M13. (3) Oligonucleotide mutagenesis in pBluescript vectors is advantageous because the mutagenized insert is located between the T3 and T7 promoters. The resultant mutant transcripts can be synthesized in vitro without further subcloning.

VCSM13 (single-strand size ~6 kb), is efficient at single-stranded DNA rescue and provides good yields of single-stranded phagemid; however it can revert to wild-type (more frequently than R408 helper phage, for example). This difficulty can be addressed by periodically propagating VCSM13 in the presence of kanamycin. [VCSM13 (a derivative of M13KO7) has a kanamycin gene inserted into the intergenic region.]
Single-Stranded Rescue Protocol

1. Inoculate a single colony into 5 ml of 2× YT broth§ containing 100 μg/ml ampicillin and VCSM13 helper phage at 10⁷–10⁸ pfu/ml (MOI ~10).

2. Grow the culture at 37°C with vigorous aeration for 1–2 hours.

3. Add kanamycin to 70 μg/ml to select for infected cells.

4. Continue growth at 37°C with vigorous aeration for 16–24 hours, or until growth has reached saturation.

5. Centrifuge 1.5 ml of the cell culture for 5 minutes in a microcentrifuge.

6. Remove 1 ml of the supernatant to a fresh tube, then add 150 μl of a solution containing 20% PEG8000 and 2.5 M NaCl. Allow phage particles to precipitate on ice for 15 minutes.

   **Note** For increased yield, perform the PEG precipitation overnight at 4°C.

7. Centrifuge for 5 minutes in a microcentrifuge. (A pellet should be obvious.)

8. Remove supernatant. Centrifuge the PEG pellets a few seconds more to collect residual liquid, then remove and discard the residual liquid.

9. Resuspend the pellet in 400 μl of 0.3 M NaOAc (pH 6.0) and 1 mM EDTA by vortexing vigorously.

10. Extract with 1 volume phenol–chloroform and centrifuge for 1–2 minutes to separate phases.

11. Transfer the aqueous phase to a fresh tube and add 1 ml of ethanol. Centrifuge for 5 minutes.

12. Remove ethanol and dry the DNA pellet.

13. Dissolve the pellet in 25 μl of TE buffer§.

*(table continues on the next page)*
### 10× Ligase Buffer
500 mM Tris-HCl (pH 7.5)  
70 mM MgCl₂  
10 mM dithiothreitol (DTT)

**Note**  *rATP is added separately in the ligation reaction.*

### TE Buffer
10 mM Tris-HCl (pH 7.5)  
1 mM EDTA  
Autoclave

### NZY Agar (per Liter)
5 g of NaCl  
2 g of MgSO₄ · 7H₂O  
5 g of yeast extract  
10 g of NZ amine (casein hydrolysate)  
15 g of agar  
Add deionized H₂O to a final volume of 1 liter  
Adjust the pH to 7.5 with NaOH  
Autoclave  
Pour into petri dishes (~80 ml/150-mm plate)

### NZY Broth (per Liter)
5 g of NaCl  
2 g of MgSO₄ · 7H₂O  
5 g of yeast extract  
10 g of NZ amine (casein hydrolysate)  
Add deionized H₂O to a final volume of 1 liter  
Adjust the pH to 7.5 with NaOH  
Autoclave

### NZY Top Agar (per Liter)
Prepare 1 liter of NZY broth  
Add 0.7% (w/v) agarose  
Autoclave

### SM Buffer (per Liter)
5.8 g of NaCl  
2.0 g of MgSO₄ 7H₂O  
50.0 ml of 1 M Tris-HCl (pH 7.5)  
5.0 ml of 2% (w/v) gelatin  
Add deionized H₂O to a final volume of 1 liter  
Autoclave

### 20× SSC Buffer (per Liter)
175.3 g of NaCl  
88.2 g of sodium citrate  
800.0 ml of deionized H₂O  
Adjust to pH 7.0 with a few drops of  
10 N NaOH  
Add deionized H₂O to a final volume of 1 liter
