Solution hybrid selection with ultra-long oligonucleotides for massively parallel targeted sequencing

Andreas Gnirke[1], Alexandre Melnikov[1], Jared Maguire[1], Peter Rogov[1], Emily M LeProust[2], William Brockman[1,5], Timothy Fennell[1], Georgia Giannoukos[1], Sheila Fisher[1], Carsten Russ[1], Stacey Gabriel[1], David B Jaffe[1], Eric S Lander[1,3,4] & Chad Nusbaum[1]

Targeting genomic loci by massively parallel sequencing requires new methods to enrich templates to be sequenced. We developed a capture method that uses biotinylated RNA 'baits' to fish targets out of a 'pond' of DNA fragments. The RNA is transcribed from PCR-amplified oligodeoxynucleotides originally synthesized on a microarray, generating sufficient bait for multiple captures at concentrations high enough to drive the hybridization. We tested this method with 170-mer baits that target >15,000 coding exons (2.5 Mb) and four regions (1.7 Mb total) using Illumina sequencing as read-out. About 90% of uniquely aligning bases fell on or near bait sequence; up to 50% lay on exons proper. The uniformity was such that ~60% of target bases in the exonic 'catch', and ~80% in the regional catch, had at least half the mean coverage. One lane of Illumina sequence was sufficient to call high-confidence genotypes for 89% of the targeted exon space.

The development and commercialization of a new generation of increasingly powerful sequencing methodologies and instruments[1–4] have lowered the cost per nucleotide of sequencing data by several orders of magnitude. Within a short time, several individual human

have been tested on target sets complex enough to match the scale of current next-generation sequencing instruments.

The first method, microarray capture[9,12,13], uses hybridization to arrays containing synthetic oligonucleotides that match the target

- Capture fragments with longest, most efficient 120-mer cRNA baits
- Probes can be designed to any regions of interest, samples can be multiplexed
- Easy to implement and compatible with validated automation solution

Contributed by Eric S. Lander, December 29, 2011 (sent for review November 22, 2011)

To gain insight into the genomic basis of diffuse large B-cell lymphoma (DLBCL), we performed massively parallel whole-exome sequencing of 55 primary tumor samples from patients with DLBCL and matched normal tissue. We identified recurrent mutations in genes that are well known to be functionally relevant in DLBCL, including *MYD88*, *CARD11*, *EZH2*, and *CREBBP*. We also identified somatic mutations in genes for which a functional role in DLBCL has not been previously suspected. These genes include *MEF2B*, *MLL2*, *BTG1*, *GNA13*, *ACTB*, *P2RY8*, *PCLO*, and *TNFRSF14*. Further, we show that *BCL2* mutations commonly occur in patients with *BCL2/IgH* rearrangements as a result of somatic hypermutation normally somatic mutations in oncogenes and tumor-suppressor genes in B lymphocytes.

Traditionally, DLBCL has been classified by the morphology and immunophenotype of the malignant B-cells but more recently, molecular classifications have been reported. Specifically, gene expression-based classification of DLBCL has been proposed (5, 6), and the prognostic relevance for this has been demonstrated (7). It has been suggested that distinct signal transduction pathways are affected in the subtypes that are defined in this way, and that certain genetic defects preferentially occur in specific subtypes defined by the presumed cell of origin of the tumors (8–12).

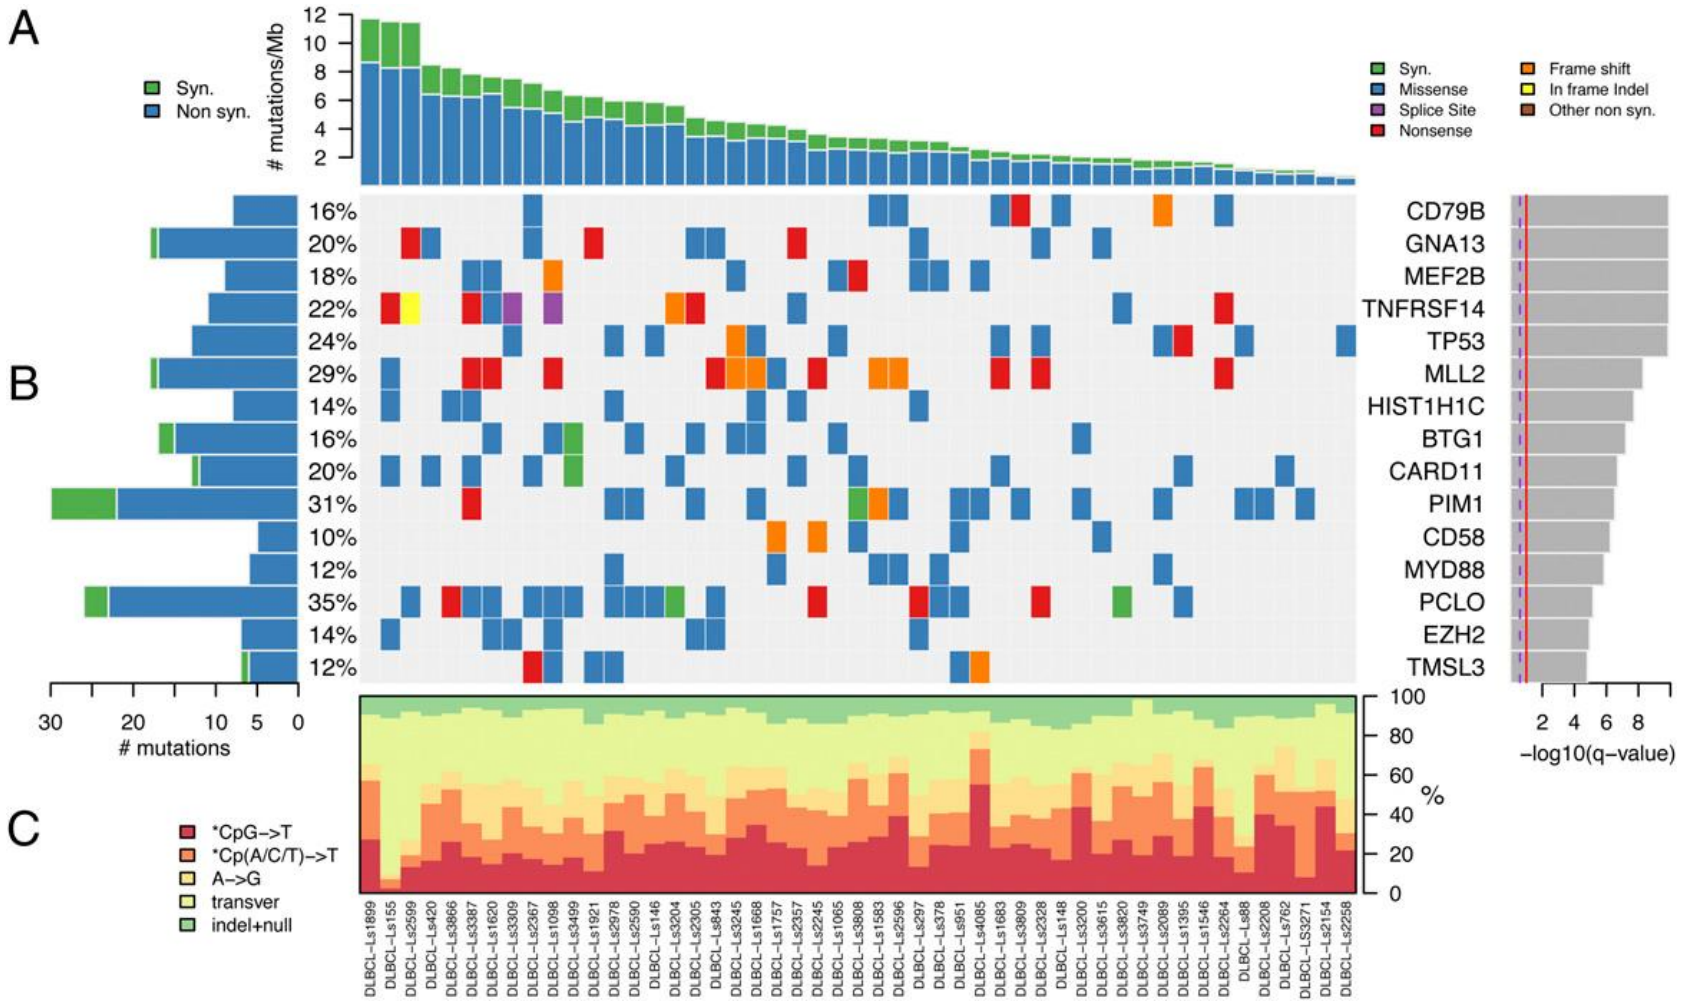
Follicular lymphoma (FL) and diffuse large B-cell lymphoma (DLBCL) are the two most common non-Hodgkin lymphomas (NHLs). Here we sequenced tumour and matched normal DNA from 13 DLBCL cases and one FL case to identify genes with mutations in B-cell NHL. We analysed RNA-seq data from these and another 113 NHLs to identify genes with candidate mutations, and then re-sequenced tumour and matched normal DNA from these cases to confirm 109 genes with multiple somatic mutations. Genes with roles in histone modification were frequent targets of somatic mutation. For example, 32% of DLBCL and 89% of FL cases had somatic mutations in *MLL2*, which encodes a histone methyltransferase, and 11.4% and 13.4% of DLBCL and FL cases, respectively, had mutations in *MEF2B*, a calcium-regulated gene that cooperates with CREBBP and EP300 in acetylating histones. Our analysis suggests a previously unappreciated disruption of chromatin biology in lymphomagenesis.

Nature 476 298-303 Aug 2011

DLBCL Exome Sequencing Details

- *Lohr et al.*
  - 55 patients paired tumor and germline(normal) DNA
  - Captured with Agilent's exome capture
  - 150-fold mean sequence coverage of targeted exons
- *Morin et al.*
  - 117 patients FL and DLBCL tumor DNA
  - Captured with Agilent's exome capture

DLBCL mutation frequency



PNAS 109 3879-3884 (2012)

Agreement between two studies

- Common Pathways and Genes Identified in Both Studies
  - Known contributing genes: *CD79B, TP53, CARD11, MYD88, EZH2*
  - Suggested Pathogenic role: *MLL2, TNFRSF14, BTG1, MEF2B, GNA13*
  - Selected Common Novel findings: *HIST1H1C, PIM1*
  - Selected Novel Findings (*Lohr et al*): *PCLO, TMSL3,*
  - Selected Novel Findings (DLBCL, *Morin et al*): *SGK1, BCL2*

Frequent nonsynonymous mutations in chromatin remodeling genes, suggesting potential cooperation in lymphomagenesis

-HDAC inhibitors under investigation (phaseI/II)

Nature 476 298-303 Aug 2011

PNAS 109 3879-3884 (2012)

Conclusions

- High Coverage of exonic content in two large cohorts of DLBCL
- Confirmed mutations in known and novel sites
- Excellent agreement between studies
- Spurred new efforts to understand potential previously unknown drivers
- Progress toward new therapeutic avenues and potentially increased survival rates

Discovery Using Target Enrichment:
Renal Cell Carcinoma

Aim:
To characterize *intra*-tumor heterogeneity that may foster tumor evolution/adaptation

Method:
SureSelect Exome sequencing of:
- 4 patient samples, 7-15 biopsies
- Pre-treatment (Primary vs. Metastasis)
- Intratumor sections (R1-R9)
- Multiple metastases

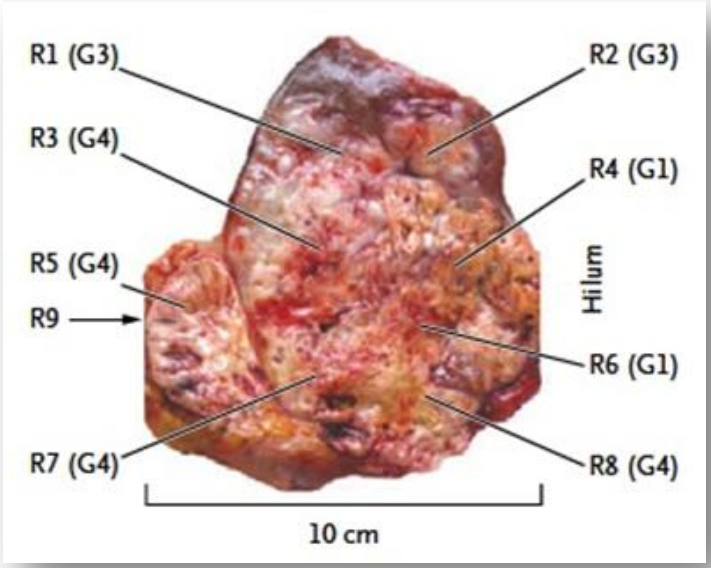
Discovery Using Target Enrichment:
Renal Cell Carcinoma

Results/Conclusions:

- Identified driver mutations (*VHL, KDM5C, SETD2, MTOR, PTEN*)
- Only *VHL* was mutated ubiquitously in all analyzed regions
- Different *regions* of the tumor have different mutations in the very *same driver* gene, e.g. *MTOR, SETD2*
- Intra-tumor heterogeneity may contribute to failure of targeted chemotherapy
- Suggests potential need for multiple assessments of tumor



Summary

- SureSelect exome target enrichment
  - Optimized probe design/production for improved capture
  - High coverage of exons with only 4Gb of sequencing
  - Samples ready for sequencing the next day

- Enables large cancer sequencing studies
  - Allows in-depth determination of nucleotide variations
  - Driving discovery of new potential targets and therapies
  - Increasing understanding of tumor evolution

Thank You!
