HOW AGILENT CROSSLAB COMPLIANCE SERVICES INTEGRATE WITH QUALITY SYSTEMS AND REGULATIONS

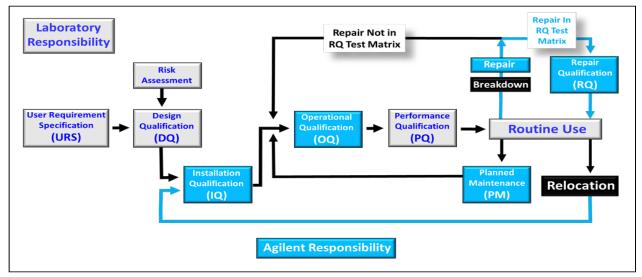

Agilent CrossLab Compliance Services

Agilent CrossLab Compliance Services

Agilent CrossLab Compliance Services are designed to seamlessly integrate with traditional quality systems used by firms and recognized by regulatory agencies worldwide. Analytical instruments must be suitable for their intended use. This requirement is good science in all laboratories and a regulatory requirement in pharma and biopharma laboratories. A life-cycle process for documenting and testing the suitability of laboratory instruments should be followed and Agilent recommends the life cycle framework defined in USP General Chapter <1058> on Analytical Instrument Qualification (AIQ). USP <1058> defines the governing framework and requirements that need to be satisfied, but the laboratory is responsible for how they satisfy these requirements.

- The United States Pharmacopoeia (USP) is the only major pharmacopeia with a general chapter dedicated to analytical
 instrument qualification, making <1058> an important global regulatory reference. The information is provided in a
 scientific, risk-based approach to analytical instrument qualification (AIQ). However, the life-cycle framework contained
 within USP <1058> is not prescriptive in its implementation, making the embedded scientific and risk-based principles
 flexible and universally applicable.
- The scientific process followed by CrossLab uses the Agilent's Automated Compliance Engine (ACE) to deliver paperless
 electronic qualification. The life-cycle stages Agilent perform are highlighted in the life-cycle diagram below. As part of
 this life-cycle, Agilent can configure the qualification tests performed to align with user requirements.

USP <1058> AIQ Framework

NOTE: RQ services, described later in this document, can be added to standard qualification services.

ACE Workflow and Equipment Qualification Plans (EQPs)

Overview

Within the ACE workflow, the qualification tests, setpoints, and limits are defined in an EQP that can be configured to ensure that testing satisfies user requirements. When the qualification work is complete, an Equipment Qualification Report (EQR) is issued. The electronic workflow used within ACE has significant data integrity advantages over traditional paper or Excel-based qualification protocols, as validated calculations can be performed directly using electronic data such as chromatograms and metrology test values. Several of the instrument life-cycle stages are the responsibility of the laboratory, Agilent can provide compliance consultancy services and documentation which can help customers satisfy these requirements. These additional services are not included in our typical qualification offering.

 $CE^{*} \circ AH = AC \circ AH =$

High-level ACE Qualification Workflow

Standard and User-defined Limits

(Hardware qualifications only)

EQPs are available for download and approval as standard documents with Agilent recommended tests, setpoints, and limits, or they can be electronically configured by approved personnel to align with user requirements and intended range of use requirements. The degree of configuration depends on the analytical technology, but most EQPs can be configured to some degree, and one feature that can typically be changed is test limits.

EQPs are designed to be configurable (dependent on the analytical technology and standard requirements), but including additional tests or setpoints can impact the qualification time and associated cost. If a test limit is changed, ACE includes the capability to report results against the Agilent approved limit and any customer required limits (that is, both can be reported simultaneously)

If a user-defined test limit is more stringent than an Agilent recommended limit, Agilent makes no guarantee or obligation regarding the instrument passing the tighter test specification requirements. It is important to appreciate that tests performed under conditions of use (that is, to satisfy pharmaceutical monograph and application requirements) can have different limits than those defined in the OQ. It is the continuum of the combined OQ, PQ, and any point of use testing performed each time the instrument is used that together satisfy regulatory requirements.

User Requirements Specification (URS)

The purpose of user requirements is to document the intended use of the instrument within the life-cycle process and quality management system (QMS) being followed. Therefore, the URS is a customer / laboratory responsibility. Defining user requirements is often used to guide the customer in instrument selection and is stated as the first activity that should be followed in <1058>. The URS is important for two main reasons.

- It is a regulatory requirement for FDA and EU GMP that the intended use of the instrument and any software must be
- Investment protection perspective means getting the right instrument for the right job.

Qualification protocols should test the instrument against any limits or specifications listed in the URS, which should document the intended range of use. Depending on the instrument complexity and how it is classified, a separate URS document may not be needed, but the URS requirements of the <1058> framework must be satisfied. A separate URS is almost always recommended for computerized systems.

An instrument performance specification is a product of the instrument development process by the supplier. It typically documents the performance the instrument can achieve. The URS should be based on intended use of the instrument and not the instrument specification. Additionally, if the intended use of a system changes, this may trigger a need to review the URS and associated qualification testing (for example, to ensure range of use is tested if used with a new analytical procedure).

Agilent offers compliance consultation services and documentation that can help customers address URS requirements.

Design Qualification (DQ)

The main function of the DQ stage of the laboratory instrument life-cycle process is to document why the selected instrument is suitable. Typically, this includes consideration of the instrument specification, how the instrument will be qualified, and the QMS followed by the instrument manufacturer. All together, these confirm that instrument performance is capable of satisfying user requirements. Depending on laboratory instrument life-cycle policy or SOPs being followed, instrument requirements and the relationship between the URS and DQ stages may vary – but as long as the <1058> framework principles are satisfied, this is not a problem, as it is left to each laboratory to justify and document its specific approaches.

The responsibility for satisfying DQ requirements primarily lies with the laboratory, with support from the supplier.

Agilent's approach to satisfying DQ requirements of USP <1058> includes the following.

- All Agilent hardware and software laboratory products, including the ACE software used to deliver qualification services, are designed, manufactured, and tested according to Agilent internal quality life-cycle development procedures.
- Certificates of Agilent testing, validation, and conformance to standards are provided with new Agilent instruments and similar certification can be provided for ACE software.
- Agilent is capable of installation, support, preventive maintenance, on-going qualification, and re-qualification after repair and user training worldwide.

Agilent offers a compliance consultation service that can help customers with DQ documentation.

Installation Qualification (IQ)

The main functions of the IQ stage are to document that laboratory is suitable (for example, critical systems typically include a site inspection / checklist), that the instrument is installed correctly in the environment, and IQ checks such as module start up are completed. IQ is provided and automated by ACE, which collects, checks, and tests Agilent hardware and software products for the following.

- 1. Purchase Order Details: Allows the customer to verify that the instrument being qualified matches their design requirements (if available) and purchase order.
- 2. Preparation and Installation Details: Gathers and records information about preparation and installation documents.
- 3. Documentation: Gathers and records information about reference and user manuals for initial installations.
- Product Quality Assurance Details: Collects and records certificates and other forms that verify that the vendor has developed and built the product according to internal standards.
- 5. Startup: Verifies that all modules/components start up properly.
- 6. Installation Verification (software only): Verifies the correctness of all installation-related files.

Operational Qualification (0Q)

The main function of the 00 stage is to evaluate and document instrument performance at the intended operational range of use. 00 protocols should include a mix of metrology, functional, and operational tests. ACE qualification protocols include information about the test description and rational, setpoints, and the limits (acceptance criteria) for each technique, category, and instrument configuration.

OQ is provided and automated by ACE. ACE checks and tests for Agilent hardware and software products include the following.

- Metrological tests such as flow, temperature, pressure, and so on that ensure that the system is performing within Agilent (or user) specifications.
- Qualification results are reported in the EQR, which can include details of all test certificates, standards, and training
 information for the engineer performing the work. (Note that the EQR can be configured to customer requirements.)
- · System or "holistic" tests verify the combined functions of the various system components
- The qualification testing can be configured to ensure URS requirements, such as range of use are tested.

For software qualification, the OQ consists of automated diagnostics regression testing and verification of the software installation. This supports continued use of the software in regulated environments (at install and as part of supporting periodic review).

In line with regulatory requirements, the EQPs should be approved before work is performed and the EQR should be reviewed and approved when the work is complete (as illustrated in Figure 2). The EQR contains all the raw data, results, and relevant information and attachments for complete compliance and traceability.

Mechanical Qualification (MQ)

(Dissolution systems only)

The main function of the MQ stage is to document that the mechanical performance of the instrument meets specifications and is functioning properly.

Performance Qualification (PQ)

The main function of the PQ stage is to document that the instrument is fit for purpose under conditions of intended use and to create an approved framework that ensures the instrument continues to perform as required. Because instrument range of use is tested within the 0Q stage, it is usually not necessary to test this during PQ. It should be noted that requirements for instrument maintenance and repair fall within the PQ life cycle stage within the USP < 1058 > framework, as they are components of ensuring the continued performance of the instrument.

The customer is responsible for satisfying PQ requirements. (NOTE: Agilent can provide a PQ for Dissolution systems only.)

It is important to note that PQ is a lifecycle activity and not a one-time event. PQ tests may include activities such as method validation or system suitability tests (SST), but in Agilent's opinion, SSTs contribute towards ensuring continued performance of the instrument (that is, PQ testing), but do may not fully satisfy <1058> PQ requirements.

Repair Qualification (RQ)

After an instrument is repaired, tests should be performed to evaluate the effectiveness of the repair and document that repaired instrument satisfies performance requirements. Agilent offers a service called Repair Qualification (RQ), which refers to the requalification of laboratory instrument hardware after a repair. For some laboratory systems, to document the performance after repair may require a full OQ. However, for some modular or component-based systems, such as HPLC and GC for example, partial qualification testing can be justified. This is accomplished by performing the qualification tests that are applicable to only the module or system component related to the repair, reducing the time the instrument is out of service. Requalifying the instrument after repair is a regulatory requirement defined in USP <1058>.

Agilent offers service contracts to repair and requalify an instrument during the period between scheduled annual OQs.

The level of retesting is prescribed in the RQ section of ACE: a form is displayed for the operator showing all types of repairs possible and the retesting required. Part of an example form for an LC system is shown below.

Re-Qualification After Repair		
Pump Strategies		
Repair/Replace Strategy	Modules	00 Testing
Internal pump head parts, active inlet valve (or AIV cartridge), (parts of) check valves, reference valves, inlet manifold or pump drive, or taking pump head apart to clean (versus repair)	Any pump	Flow Accuracy & Precision
Pulse damper, pressure transducer	Any pump	Flow Accuracy & Precision
Multi-channel gradient valve	Quaternary	Flow Accuracy & Precision Gradient Composition

The full list of RQ repair and retest guidance is available for customer review.

SERVICE DELIVERY METHODS

CUSTOMER APPROVAL OF ALTERNATIVE METHOD AND EQR STORAGE

Agilent CrossLab Compliance Services

Overview

Agilent recommends use of **Network ACE** for CrossLab qualification services that are enabled using the Agilent Automated Compliance Engine (ACE) software. Network ACE and Local ACE both access data directly (default methods) and are considered equivalent from a data integrity and data traceability perspective (see below). To provide additional flexibility in qualification service delivery, an alternative method is also available that accesses data indirectly. Use of the alternative method requires customer pre-approval using this form.

Available Methods

Method	Definition
Network ACE (Agilent recommended)	ACE software is installed on a network node within the laboratory LAN infrastructure. Raw data locations are always captured in the equipment qualification report (EQR), which provides end to end traceability and a fully characterized data workflow in the delivery. This method requires collaboration with the customer to load ACE behind the customer firewall.
Local ACE	ACE software resides on an independent external drive that can be driven from the system controller, where the customer data system (CDS) resides. Because the external drive is connected to the CDS, the data integrity of this method is equivalent to that of the Network ACE delivery method. Raw data is imported directly into ACE by the Data Manager tool, with the data paths always captured in the report, which provides data traceability assurance.
Alternative (Requires pre-approval)	 This method requires customer pre-approval due to data integrity implications. Only choose this option in scenarios like the following: ACE software is not run from a PC directly connected to the customer CDS, such as the FSE's laptop. System data files are transferred indirectly from the CDS to the FSE laptop instead of directly as done with Network and Local ACE methods. Data is acquired using a CDS on the FSE's laptop and transferred directly to ACE. The CDS used in this method is qualified for data collection purposes.

EQR Storage

Select the checkbox below to authorize Agilent to store copies of the EQRs generated by ACE for Agilent internal assessments. The intention of the assessment is to evaluate the delivery of the qualification service, with a focus to improve delivery and assess the appropriateness of data integrity measures. The storage is exclusively for the internal assessment by Agilent and is not shared with other organizations. It is not to be considered a backup for the EQR provided at qualification delivery.

Customer Appr	oval of Alternative Method and EQR Storage
Authorize Agilent to	use the alternative method (check for approval):
Authorize Agilent to	store EQRs for their internal assessment (check for approval):

AGILENT CROSSLAB QUALIFICATION SERVICES

USE CASES FOR SERVICE DELIVERY

Agilent CrossLab Compliance Services

Introduction

With heightened scrutiny of data integrity, the Agilent Automated Compliance Engine (ACE) software must be able to access instrument-generated raw data files one of two ways: directly, using the connection between network nodes or with the server; and indirectly, through storage in a secure transfer location. (In this document, data integrity refers to the who, what, and where of data used in generating an ACE equipment qualification report, or EQR.)

ACE includes three main service delivery methods that address data integrity requirements; the rest of this document provides details to determine which one best fits a customer's needs.

Regardless of the delivery method, ACE features and delivery procedures are compatible.

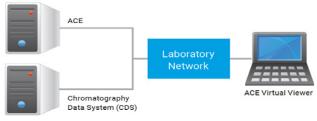

Network ACE (Agilent Recommended)

Overview

ACE software is installed on a network node within the laboratory LAN infrastructure, which requires collaboration with the customer to load ACE behind their firewall. Raw data locations are always captured in the EQR, which provides end-to-end traceability and a fully characterized data workflow in the delivery.

Details

Typical Network ACE installation diagram

Installing ACE in a separate node (a.k.a. the host PC) on the same network as the system controller offers data traceability that is equivalent to an installation on the system controller itself. The system controller (where the CDS resides) and the ACE host PC are identified and seen by the server and subject to the customer's data access controls and general IT policies. The CDS's audit trail records data movements between nodes or between the client and server, and ACE's data traceability features identify the original data directory and therefore ensures end-to-end data traceability

The ACE host PC has a separate/partitioned drive for ACE

software. During ACE's installation, two services are setup on the operating system (OS): one for security and the other as a watchdog. Because the ACE host PC sits on the network as a shared drive, engineers access ACE through the networked drive: ACE is not installed on ACE Virtual Viewer PCs.

Requirements

Installation

- Install on a host PC with a separate drive (different from that of the OS)
- Attach to a network that clients can access
- 500 GB
- NTFS format
- User has local administration rights
- Customer installation instruction document is available

Operational

- User has an ACE node logon with a minimum of power user rights permissions; user also has a personal ACE account and password added through the ACE licensing tool
- Up to 5 users with 3 open sessions each can access the NDA simultaneously
- Exception to ports 11121-11141 on ACE node, clients, and switch's/Smart Hubs to be open on the network

Local ACE

Overview

ACE software resides on an independent drive that can be driven from the system controller, where the CDS resides. Because the drive is connected to the CDS, this method's data integrity is equivalent to preferred 1 method's. Raw data is imported directly into ACE by ACE's Data Manager tool, and data paths are captured in reports to provide data traceability.

ACE software resides on an independent drive that can be driven from the system controller, where the CDS resides. Because the drive is connected to the CDS, this method's data integrity is equivalent to the Network ACE method. Raw data is imported directly into ACE by ACE's Data Manager tool, and data paths are captured in reports to provide data traceability.

Details

ACE is designed to run from a dedicated drive, without leaving a footprint on the host PC. Therefore, it can be connected directly to the system controller (where the CDS resides) without altering the system's qualification status. For additional protection, the drive can be driven by another host PC on the same network; also, the drive can remain on site with the customer for use by the Agilent Field Service Engineer (FSE) during service deliveries only.

Alternative Method

This method requires customer pre-approval due to data integrity implications and only applies in scenarios like the following:

- ACE software is not run from a PC directly connected to the customer CDS, such as the FSE's laptop. System data files are
 transferred indirectly from the CDS to the FSE laptop instead of directly as done with Network and Local ACE methods.
- Data is acquired using a CDS on the FSE's laptop and transferred directly to ACE. The CDS used in this method is qualified for data collection purposes.

MICROFLUIDICS BIOANALYZER HARDWARE

OPERATIONAL QUALIFICATION

Agilent CrossLab Compliance Services

Standard 00 Test Suite

This document describes the test program for qualifying Agilent Bioanalyzer systems.

The following table lists all automated tests run from software that controls the instrument; listed setpoints and limits are internal to that software and cannot be changed for the 00.

Key:Test names with an E apply to systems with electrode cartridges; test names with a P apply to systems with pressure cartridges.

Test	Setpoints and Parameters	Limits
CDS Logon Verification (E, P)	N/A	Evidence of logon used to collect qualification data
System Preparation (E, P)	N/A	N/A
Electronics (E, P)	N/A	N/A
Lid Sensor (E, P)	N/A	N/A
Temperature Accuracy and Stability (E, P)	Temperature: 40°C Stability is measured over 45 seconds.	Time to reach target temp $\leq 300~s$ Difference between high and low temps $\leq 0.6^{\circ}\text{C}$ Stability mean $\geq 39^{\circ}\text{C}$ and $\leq 41^{\circ}\text{C}$ Difference between external and internal ambient temps $\leq 10^{\circ}\text{C}$ Difference between external and internal chip temps $\leq 3.2^{\circ}\text{C}$
HV Stability and Accuracy (E)	250 V 500 V 1000 V 1500 V	Mean deviation from target voltage \pm 10 V Difference between high and low values \leq 10 V
HV Accuracy On-load (E) (N/A for G2939B)	Tested at 0.5 μA	Voltage decay ≤ 15%
HV Precision (E)	500 V 1000 V 1500 V	Difference between mean and target voltages $\leq 10~\text{V}$ Relative standard deviation $\leq 0.2\%$
Short Circuit (E)	N/A	Leakage mean for each channel $\leq 0.025~\mu A$
Electrode/Diode (E)	N/A	Current for channels 2 to 16 \leq -1.5 μA
Optics (E) (G2939A and G2939B test the laser; other modules test the laser and LED)	N/A	Absolute value for dark current of red laser \leq 15 FU Absolute value for dark current of blue LED \leq 15 FU Absolute value for diffuse light of red laser \leq 30 FU Absolute value for diffuse light of blue LED \leq 30 FU
Electrophoresis Autofocus (E)	N/A	Horizontal offset \leq 320 steps Vertical offset \leq 250 steps Red laser intensity compared to installed chip intensity \geq 25%
Laser Stability (E) (not scheduled for MF.01.03 and later)	N/A	Drift for red laser signal $\leq 5\%$ Peak-to-peak amplitude of red laser's ripple signal $\leq 0.5\%$
Pressure Offset (P)	Monitored for 40 seconds after cartridge is removed	Pressure ≥ -50 mbar and ≤ 50 mbar
Pressure Control (P)	N/A	Time to reach -140 mbar \leq 250 measured points Mean pressure \geq -142 mbar and \leq -138 mbar Difference between high and low pressures \leq 5 mbar

Test	Setpoints and Parameters	Limits
System Leakage (P)	Monitored for 30 seconds after pump stops	Pressure drop ≥ -105 mbar and ≤ -75 mbar
Autofocus Flow Cytometry (P)	N/A	Drive step \geq 1248 steps/mm and \leq 1268 steps/mm Position of first peak \geq -2530 steps Position of last peak \geq 1840 steps
Finalize (E, P)	N/A	N/A

Test Design and Rationale

Overview

Many GMP/GLP enforcement agency inspectors now ask firms to provide a risk assessment of their equipment and computer systems plus a science-based rationale for subsequent validation and qualification testing.

GENERAL RISK STATEMENT: Any laboratory chemical system used for raw material testing or final drug product / medical device testing in GMP or used in formal GLP studies will likely fall into a HIGH RISK category. This risk assessment will imply the need for IQ & OQ & on-going qualification. ANY USER SPECIFIC RISK ANALYSIS SUPERCEDES THIS GENERAL RISK STATEMENT.

The rest of this section outlines the science-based rationale for each test in the Agilent hardware 00 plus a brief test design and procedure description.

The recommended set of hardware OQ tests described in this EQP derives from Agilent's interpretation of FDA, USP, and GAMP guidelines and other authoritative expert literature.

OQ test design incorporates both modular and holistic testing, which is a proven and regulatory acceptable approach. When applicable, direct metrology is used to test pump flow rates and thermal-controlled column compartments, for example. Holistic chemical testing is used to evaluate critical instrument characteristics

When applicable, certified reference standards and calibrated equipment are used.

Considering the number of setpoints, parameters, and conditions of each recommended 00 test, the proven concepts of worst case, range, and representative have been applied. If a property or characteristic is known to have its worst performance at one end of a range of use, this is the setpoint that should be tested and other setpoints are not required. If a property or characteristic has no known worst case, testing at the high and low points of the range of use is required. If there are too many possible use cases and conditions to realistically test (and none is a worst case), a representative sample for test is the best approach.

CDS Logon Verification

Description: To satisfy the attributable requirement of ALCOA+, evidence of the logon used to collect data must be provided.

Procedure: The test uses a screen capture to document who is logged on to the software that controls the instrument being qualified. The capture is automatically included with this test in the EQR.

System Preparation

Description: This test prepares the system for qualification; it does not test system performance.

This test applies to systems with electrode and/or pressure cartridges.

Procedure: Clean the cartridge, configure the system, and create a new verification in the 2100 Expert software.

Electronics

Description: This test verifies communication with the instrument. It sends a checksum command to the instrument and checks the response. An incorrect response means no communication with the instrument.

This test applies to systems with electrode and/or pressure cartridges.

Procedure: Run the automated test. After the test is completed, a pass/fail status is determined automatically.

Lid Sensor

Description: This basic safety test identifies the type of cartridge installed and whether the lid is closed. A voltage or pressure cannot be applied to the cartridge and the laser cannot be turned on if the lid is open.

This test applies to systems with electrode and/or pressure cartridges.

Procedure: Run the automated test. After the test is completed, a pass/fail status is determined automatically.

Temperature Accuracy and Stability

Description: This test verifies the instrument internal temperature sensors for the heater plate and ambient sensor using an external thermometer.

This test applies to systems with electrode and/or pressure cartridges.

Procedure: Run the automated test. When the measurements are valid, it ramps the heater plate temperature to 40°C and monitors it using the bioanalyzer's internal sensor. The setpoint must be reached within a certain time period and then maintained for an additional 45 seconds. Temperature stability is calculated as the delta between the highest and lowest temperatures. After the test is completed, a pass/fail status is determined automatically.

HV Stability and Accuracy

Description: This test verifies the high voltage controller at four voltages.

This test applies to systems with electrode cartridges.

Procedure: Run the automated test. It sequentially sets all 16 channels to a nominal voltage, measures the voltage of each channel and the reference channel (channel 17), and calculates (1) deviation of the nominal voltage from the measured voltage for channels 1 to 1, (2) maximum channel-to-channel deviation for channels 1 to 16, and (3) deviation of the nominal voltage from the measured voltage for the reference channel. After the test is completed, a pass/fail status is determined automatically.

HV Accuracy On-load

Description: This test verifies the channel-reference diode in transmission mode at three voltages.

This test applies to systems with electrode cartridges.

Procedure: Run the automated test. It sets the reference channel (channel 17) to a nominal voltage, sequentially sets all 16 channels to -0.5 microA, measures the voltage, and calculates the deviation of the reference (on-load) channel voltage from the measured voltage. After the test is completed, a pass/fail status is determined automatically.

HV Precision

Description: This test verifies the high voltage accuracy for three voltages.

This test applies to systems with electrode cartridges.

Procedure: Run the automated test. It calculates the average and relative standard deviation (RSD) for six runs within each voltage. After the test is completed, a pass/fail status is determined automatically.

Short Circuit

Description: This test measures the leak current for the channels 1 through 16 separately when a nominal voltage of 1500 volts is applied to each one.

This test applies to systems with electrode cartridges.

Procedure: Run the automated test. For each channel, it measures the current for three seconds and then calculates the average leak current. After the test is completed, a pass/fail status is determined automatically.

Electrode/Diode

Description: This test measures the cumulative current for the channels 2 through 16.

This test applies to systems with electrode cartridges.

Procedure: Run the automated test. It sets channel 1 to 100 volts and all other channels to -2 microA, and each reported value must be lower than the limit for this test to pass. After the test is completed, a pass/fail status is determined automatically.

Optics

Description: This test measures the dark current and stray light for the laser and LED.

This test applies to systems with electrode cartridges.

Procedure: Run this automated test. After the test is completed, a pass/fail status is determined automatically.

Electrophoresis Autofocus

Description: This test verifies the bioanalyzer's horizontal and vertical offsets.

This test applies to systems with electrode cartridges.

Procedure: Run the automated test. It performs an autofocus, measures horizontal and vertical offset values, and then checks the offset values against the limits after being corrected for the offset value displayed on the autofocus (electrophoresis assay) chip. After the test is completed, a pass/fail status is determined automatically.

Laser Stability

Description: This test verifies the stability of the red laser signal.

This test applies to systems with electrode cartridges.

Procedure: Run the automated test. It executes an autofocus run and then, for an additional 45 seconds at a data rate of 20 Hz, collects 900 data points to use for the stability calculation. After the test is completed, a pass/fail status is determined automatically.

Pressure Offset

Description: This test verifies a proper pressure offset which is required to run the pressure control and system leakage tests without ambiguous results.

This test applies to systems with pressure cartridges.

Procedure: Run the automated test. It requires that the pressure cartridge is removed from the instrument so that the pressure is around 0 mbar. For 40 seconds, the pressure is monitored and must be within the minimum and maximum values. The offset is adjusted to 0 mbar and the pressure monitored until the end of the run. When pressure is outside this range, the offset cannot be adjusted and the test will fail. After the test is completed, a pass/fail status is determined automatically.

Pressure Control

Description: This test monitors the time it takes to reach the specified pressure.

This test applies to systems with pressure cartridges.

Procedure: Run the automated test. When the pressure is reached, it must remain stable for the duration of the run, which is as long as the pump runs. After the test is completed, a pass/fail status is determined automatically.

System Leakage

Description: This test verifies that the pump is leak tight.

This test applies to systems with pressure cartridges.

Procedure: Run the automated test. At -100 mbar, the pump stops running and the pressure is monitored for an additional 30 seconds. After the test is completed, a pass/fail status is determined automatically.

Autofocus Flow Cytometry

Description: This test scans the flow cytometry autofocus chip and must find at least five of seven paths present on the chip.

This test applies to systems with pressure cartridges.

Procedure: Run the automated test. After the test is completed, a pass/fail status is determined automatically.

Finalize

Description: In this test, the final report is collected and the qualification is finalized.

This test applies to systems with electrode and/or pressure cartridges.

Procedure: Create and attach the 2100 Expert software report to the EQR; record report page numbers in the EQR for reference.
