Further, to the maximum extent permitted by applicable law, Agilent disclaims all warranties, either express or implied, with regard to this manual and any information contained herein, including but not limited to the implied warranties of merchantability and fitness for a particular purpose. Agilent shall not be liable for errors or for incidental or consequential damages in connection with the furnishing, use, or performance of this document or of any information contained herein. Should Agilent and the user have a separate written agreement with warranty terms covering the material in this document that conflict with these terms, the warranty terms in the separate agreement shall control.

Technology Licenses

The hardware and/or software described in this document are furnished under a license and may be used or copied only in accordance with the terms of such license.

Restricted Rights Legend

If software is for use in the performance of a U.S. Government prime contract or subcontract, Software is delivered and licensed as “Commercial computer software” as defined in DFAR 252.227-7014 (June 1995), or as a “commercial item” as defined in FAR 2.101(a) or as “Restricted computer software” as defined in FAR 52.227-19 (June 1987) or any equivalent agency regulation or contract clause. Use, duplication or disclosure of Software is subject to Agilent Technologies’ standard commercial license terms, and non-DOD Departments and Agencies of the U.S. Government will receive no greater than Restricted Rights as defined in FAR 52.227-19(c)(1-2) (June 1987). U.S. Government users will receive no greater than Limited Rights as defined in FAR 52.227-14 (June 1987) or DFAR 252.227-7015 (b)(2) (November 1995), as applicable in any technical data.

Safety Notices

CAUTION

A CAUTION notice denotes a hazard. It calls attention to an operating procedure, practice, or the like that, if not correctly performed or adhered to, could result in damage to the product or loss of important data. Do not proceed beyond a CAUTION notice until the indicated conditions are fully understood and met.

WARNING

A WARNING notice denotes a hazard. It calls attention to an operating procedure, practice, or the like that, if not correctly performed or adhered to, could result in personal injury or death. Do not proceed beyond a WARNING notice until the indicated conditions are fully understood and met.
In This Guide...

This manual covers the InfinityLab LC Method Development Solutions, for example the 1260 Infinity II and 1290 Infinity II LC method development solutions. An LC method development solution consists of the corresponding hardware setup and the Method Scouting Wizard.

1 Prerequisites for the LC Method Development Solution

This chapter gives information on Prerequisites for the LC Method Development Solution.

2 The Method Development System

This chapter gives information on hardware system components, column and solvent switching.

3 System Setup and Installation

This chapter provides information on system setup, installation of valve heads, heat exchangers and capillaries, and installation of solvent selection parts.

4 Configuring the System in ChemStation and Creating Methods

This chapter explains how to configure the system in the control software and how to create methods.

5 The Agilent ChemStation Method Scouting Wizard

This chapter provides information on installation, use and features of the software.

6 Method Development Strategy

This chapter provides information on method development strategy, concerning LC and LC/MS columns selection, pH and mobile phase.

7 Appendix

This chapter provides addition information on safety, legal and web.

This chapter gives information on Prerequisites for the LC Method Development Solution.
Prerequisites for the LC Method Development Solution

High Pressure Liquid Chromatography (HPLC) allows the efficient separation of compounds and therefore is a key technology in pharmacology and chemistry. The interaction of analyte molecules with so-called stationary and mobile phases determines the compound separation. Developing the optimal method for different compounds can be quite demanding. There are almost endless possible combinations of crucial parameters like solvent type, column type, temperature, and gradient.

The InfinityLab LC Method Development Solutions (Meth Dev) allows simple generation of a sequence that varies all crucial method parameters systematically. The Meth Dev is based on a skilled soft- and hardware configuration.

Hardware Configuration

The system consists of a 1260 Infinity II or 1290 Infinity II LC with the following options:

- Single Multicolumn Thermostat (MCT) solution with one MCT module.
- A valve thermostat cluster (VTC) with multiple valve hosts (Multicolumn Thermostats, Valve Drives, Thermostatted Column Compartments) and temperature zones (Multicolumn Thermostats, Thermostatted Column Compartments, Integrated Column Compartments) (1290 Infinity II only).

(For a list of all supported modules see Table 2 on page 17.)

Functions of the hardware:

- Solvent delivery that is combined with external solvent selection:
  - Variation of liquid phase and generation of gradients
- Column compartment:
  - Determination of temperature
- Column selection:
  - Variation of stationary phase
Software Configuration

The ChemStation Method Scouting Wizard A.02.08 is an Add-on for OpenLAB CDS ChemStation.

The Method Scouting Wizard automatically generates all steps to flush the system with any required solvents, performs column equilibration procedures, and defines storage conditions for columns in predefined storage solvents. In this respect, it uses waste and/or available bypass lines intelligently to allow fast flushing procedures. Flushing, equilibration and column storage procedures, and temperature changes are arranged in the workflow such that a minimal number of these steps need to be performed to save valuable time and solvents. The Method Scouting Wizard requires the following software components:

- OpenLAB CDS ChemStation Edition C.01.08, Workstation

NOTE

Not supported: Secure Workstation and Distributed AIC

- LC & CE Drivers A.02.18

NOTE

Make sure that driver version A.02.18 is installed:

- Check the installed driver version with your OpenLAB CDS ChemStation Edition C.01.08.
- Upgrade or downgrade if the driver version is different.

For details on the possible hardware configurations, see Table 2 on page 17.

For details on the software requirements, see “Overview of the Agilent Method Scouting Wizard” on page 74.

\(^1\) A cluster of two
Solvent delivery

For increased solvent selection capability pumps can additionally be equipped with external solvent selection valves. This extends the number of available solvents on one pump channel to a maximum of 12. See Figure 1 on page 13 as an example.

Figure 1 Method development system principle with external solvent solution
External solvent selection

The external solvent selection valve consists of a 1290 Infinity Valve Drive (G1170A) in combination with a G4235A 12-Pos/13-Port Solvent Selection Valve Head.

**NOTE**
If two external solvent selection valves are configured, they must both be connected either before or after the degasser. Connection of one valve on either side of the degasser is not supported.

For further details and examples refer to chapter *System Setup and Installation*.

Solvent Switching

In addition to the two or four solvents directly supported by the pump, up to two ports of the pump can be connected to an external Valve Drive (G1170A) equipped with a 12-position/13-port solvent selection valve head (G4235A). This valve is able to switch between up to 12 solvents giving a total of up to 26 solvents on the Method Development System.

An overview of the components required for solvent selection depends on the system:

- Agilent InfinityLab LC Series Systems:
  - “Components for Solvent Selection (Agilent Infinity-II LC)” on page 18
- Classic Systems:
  - “Components for Solvent Selection (Agilent 1290 Infinity LC)” on page 30
  - “Components for Solvent Selection (Agilent 1260 Infinity LC)” on page 32

All Agilent pumps are delivered together with one solvent cabinet and as many solvent reservoirs as available solvent channels of the pump (two or four). For Agilent 1260 Infinity Binary Pumps the built-in solvent selection option is recommended.

For the selection of the degasser and the number of degassers in a system, refer to “Deciding on the Position of the Degasser” on page 51.
Sample introduction

Any of the Autosamplers supported by LC&CE Drivers A.02.18 can be used (see Table 2 on page 17). Select your autosampler suitable to the required maximum pressure capability of the system.

Column compartments

For the temperature zones there is a great variety of possibilities. Up to eight short (or four long or four short and two long...) columns can be used with one 1290 Infinity II Multicolumn Thermostat (G7116B) (single MCT). With a valve thermostat cluster (VTC) of up to four 1290 Infinity II Multicolumn Thermostat (G7116B) modules it is possible to use up to 32 columns. In addition to that, it is possible to combine a multicolumn thermostat with other components such as ICC (G7130A).

For further details and examples refer to chapter System Setup and Installation.

Column selection

Several valve hosts like G7116A (MCT), G7116B (MCT) or G1170A (1290 Infinity Valve Drive) can be used for column selection. For the compatible valves heads/valve kits see Table 2 on page 17.

Sample detection and analysis

A very broad range of detectors is supported, including light detectors (UV, DAD, FLD), mass selective detectors, evaporative light scattering detectors and refractive index detectors. Other detectors, for example chiral detectors, can be used by acquiring the signal via an analog to digital converter.
Capillary Kits

For use with MCT the following capillary kits are available:

- Capillary Kit, 0.12 mm (5067-4248) for 8-column selector with Quick-Connect heat exchangers (standard flow), see “Capillary Kit for 8 Columns in one 1290 Infinity II MCT” on page 19.

- Capillary Kit, 0.12 mm, 8-column sel, long columns, PCHex (5067-6697) to cluster two MCTs, if long columns are used (see “Capillary Kit for 8 Columns >150 mm in two 1290 Infinity II MCTs” on page 21).

- Cap kit 0.12 mm, 4-col, incl. QC-HE (5067-6596) for 4 columns in one 1260 Infinity II MCT (see “Capillary Kits for 4 Columns in one 1260 Infinity II MCT” on page 26).

For use with TCC the following capillary kits are available:

- Cap Kit 0.12 mm LDHE double 8/9 vlv short col (5067-6220), see “Low Dispersion Capillary Kit for Short Columns” on page 36

- Cap Kit 0.12 mm LDHE double 8/9 vlv long col (5067-4289), see “Low Dispersion Capillary Kit for Long Columns” on page 38

- Cap Kit 0.17 mm 8/9 multi purpose (5067-4290), see “General Purpose Capillary Kit” on page 37

The capillary kit that is used depends on the columns to be installed.

All kits, and all components of the kits, can be ordered separately as consumables.
The Agilent 1290 Infinity II Method Development System

**Column Selection**

**Column Selection with one G7116B (single MCT)**

To perform automated column switching with the Method Development System, one 1290 Infinity II Multicolumn Thermostat equipped with a column selector valve head is required. For a 8 column selection valve (G4239C), a maximum of eight positions are available to connect columns, bypass, or waste lines. By using the Agilent low dispersion heat exchanger, up to eight solvent streams can be pre-heated to a maximum of 110 °C, depending on the flow rate.

The Method Development System
The Agilent 1290 Infinity II Method Development System

Column Selection in a Valve Thermostat Cluster (VTC)

A valve thermostat cluster (VTC) is a powerful solution to automatically switch between up to 32 columns in a system. Different topologies allow multiple combinations of valve hosts (Multicolumn Thermostats, Valve Drives, Thermostatted Column Compartments) and temperature zones (Multicolumn Thermostats, Thermostatted Column Compartments, Integrated Column Compartments). The recommended VTC topologies are described in the following.

NOTE

Agilent 1260 Infinity II Multicolumn Thermostat (G7116A) does not support clustering!
**A Valve Thermostat Cluster (VTC) for long columns**

This most simple VTC topology is needed for clustering one valve with a column host (one or two Column Compartments). With two MCT it is possible to use up to 8 long columns (or any combinations of long and short columns).

It is also possible to use this topology with a valve in an external valve drive and an ICC.

**Capillary Kit for 8 Columns >150 mm in two 1290 Infinity II MCTs**

Capillary Kit, 0.12 mm, 8-column sel, long columns, PChex (5067-6697):

</tbody>
</table>
A Valve Thermostat Cluster (VTC) for up to 32 Columns

In the valve thermostat cluster, the described VTC solution (see “A Valve Thermostat Cluster (VTC) for long columns” on page 21) can be multiplicated up to four times. These branched topologies are typically realized via an external valve and some MCT modules, each equipped with an 8-column selection valve.

NOTE

The number of branches is fix. If a topology with four branches is selected, four valves have to be configured in the branches - plus one branching valve (root valve).

Column Selection

Column Selection with two to three TCC

To perform automated column switching with the Agilent 1200 Infinity Series Method Development System, two 1290 Infinity Thermostatted Column Compartments (G1316C), each equipped with an 8pos/9port valve, are required. A maximum of eight positions are available to connect columns, bypass, or waste lines. By using the Agilent low dispersion heat exchanger, up to eight solvent streams can be pre-heated to a maximum of 100 °C (G1316C), depending on the flow rate. If six columns longer than 100 mm have to be installed and solvent pre-heating is required, either 3x G1316C or 2x G1316C and 1x G1316A/B are necessary.

For automated column switching, the following parts and modules have to be integrated:

Two different valve kits are available:
- The G4230A valve kit is required for Agilent LC systems with specified pressure range of up to 600 bar. The kit contains two 8-position/9-port valve heads (Valve Head 8 Position/9 Port, 600 bar (5067-4107)) rated to a maximum pressure of 600 bar.
• The G4230B valve kit is required for an Agilent 1290 Infinity LC, and contains two different valve heads:
  • On the column inlet side, an ultra-high-pressure-rated 8-position/9-port valve head that is rated to a maximum pressure of 1200 bar (Valve Head 8 Position/9 Port, 1200 bar (5067-4121)) is necessary;
  • on the column outlet side, only little backpressure is given and a standard 600 bar selection valve (Valve Head 8 Position/9 Port, 600 bar (5067-4107)) is sufficient.

One of three available capillary kits is delivered along with the valve kit.
Infinity Capillary Kits

Low Dispersion Capillary Kit for Short Columns

The components of the low dispersion capillary kit for short columns (Cap Kit 0.12 mm LDHE double 8/9 vlv short col (5067-6220)) are listed below.

Valve 1 refers to the inlet valve and Valve 2 refers to the outlet valve.

This chapter provides information on system setup, installation of valve heads, heat exchangers and capillaries, and installation of solvent selection parts.
The Method Development System works in lots of different hardware configurations. For details of the individual modules mentioned in this guide, refer to the Agilent Information Center (AIC).
The Method Development System works in lots of different hardware configurations. Examples for different proved and tested method development system set-ups are shown in Figure 7 on page 41, Figure 8 on page 42, and Figure 9 on page 43.

**Figure 7**  Example setup based on a 1290 Infinity II LC
3 System Setup and Installation
System Setup

Figure 8 Example setup based on an Agilent 1260 Infinity Multisampler with Quaternary Pump G1311B
In principle, the connecting capillaries should be kept as short as possible to reduce extra-column band-broadening, and to keep the backpressure small. It is very important to keep the distance to the detector as short as possible. The next important connection is from the autosampler to the column compartment. Several set-ups taking these considerations into account are covered with the available capillary kits.
Configurations and Capillary Setup

Configuration and Capillary Setup (G7116B)

**CAUTION**

Damage to the rotor seal

Instant pressure release within the valve will lead to water jet effects that can harm internal parts of the valve. This pressure release typically happens if the valve gets switched under high pressure over unused or open channels.

➔ Block all unused channels properly with the M4 blank nut.

**NOTE**

To minimize valve movement over open connections it is recommended to plumb the column connected channels in one row.

e.g.:

- channel 1 – column 1
- channel 2 – column 2
- channel 3 – column 3
- channel 4 – column 4
- channel 5 – blocked
- channel 6 – blocked
- channel 7 – waste
- channel 8 – bypass

**NOTE**

The blank nuts are only required for the ports on the inner circle that connect the valve with the column inlet.
1. Install the in and out connectors.
   - from sampler to the valve (Capillary ST 0.12 mm x 500 mm M4-SL PS-PS (5500-1202))
   - from valve to the detector (Capillary ST 0.12 mm x 280 mm M4-SL PS-PS (5500-1203))

   ![Diagram of valve connections]

   The In port is hydraulically connected to the column inlet ports 1-8 on the inner ring while the Out port connects to the column outlet ports 1'-8' on the outer ring.

2. Install the column inlet and outlet connections.

   **ports 1-8** for connections from valve to the heat exchanger (Capillary ST 0.12 mm x 130 mm M4-SL PS-PS (5500-1199)) or waste line (Waste tube (G1375-87326))

   **ports 1'-8'** for connections from column outlet to valve (Capillary ST 0.12 mm x 130 mm SL/M (5500-1200)), use fingertight PEEK fittings for connecting the column outlet

   ![Diagram of column connections]
Setup Examples

1 8 Column-selection

Figure 10  Hydraulic flow path schematics for an 8-column selection setup
2 Six column selection with purge line and valve- bypass

Figure 11 Hydraulic flow path schematics for 6-column selection setup with purge and valve bypass line.
Recommended Column Configurations

Column Configurations with one MCT

The column configurations with the MCT are very flexible and cover most of the major requirements for method development. MCT configurations with a Column Selector Valve and Quick Connect Heat Exchangers offer the following options:

- Quick change between up to eight (G7116B) respectively four (G7116A) different columns of 100 mm length
- Different stationary phases for different applications, or
- Identical stationary phases in columns with different dimensions for either faster run-times or higher resolutions, or
- Different internal diameters for loading studies
- Two independent heating zones for four columns each (heating room divider strongly recommended)

Figure 12   The G7116B 1290 Infinity II Series Multiple Column Thermostat equipped with a Quick-Change 8 Column Selector Valve
**Column Configurations with two MCT (for long columns)**

The same situation as described in “Column Configurations with one MCT” on page 48 can be achieved using two MCT modules and one valve. In this configuration it is possible to use up to 8 long columns (or several combinations with short columns). If more columns are needed, see “A Valve Thermostat Cluster (VTC) for up to 32 Columns” on page 22.

**NOTE**

Agilent 1260 Infinity II Multicolumn Thermostat (G7116A) does not support clustering!
Installing the Solvent Selection Part

Especially for LC method development, but also for frequently changing application needs, it is very important to have a large choice of different mobile phases available because the pH value, the organic modifier, and the ionic strength have a large influence on the separation. Therefore, the Agilent Method Development Systems offers the possibility to equip the pump with up to two additional external valve drives (G1170A), equipped with a 12-position/13-port solvent selection valve head (G4235A). This multiplexes a channel of the pump and provides up to 12 additional solvent channels. With the quaternary pump, this gives a maximum of 26 available solvents and allows the generation of up to 169 solvent combinations (for a binary gradient), or 288 unique solvent combinations (for ternary gradients). When the external solvent selection valves are combined with a binary pump with no internal solvent selection valve, 144 solvent combinations are possible. If the binary pump is fitted with an internal solvent selection valve, providing two different solvents per channel, up to 169 solvent combinations (for a binary gradient) are possible. For an overview, see Table 4 on page 50.

</table>
Deciding on the Position of the Degasser

It is recommended to use the built-in degassing unit, and to place it in the flow path behind the external solvent selection valve. The built-in degassing unit has a low delay volume and a very high degassing efficiency.

The Agilent 1260 Infinity Binary Pump (G1312B) does not have a built-in degasser. For Agilent 1260 Infinity Binary LCs, you need to decide where in the flow path to position the external degassing unit. There are two options available: Solvent degassing can be done before or after the external solvent selection valve.

NOTE

If two external solvent selection valves are configured in the system, only degassing either before or after the external solvent selection valve is supported. A configuration with one valve before the degasser and one after it is not supported.

Degassing before the solvent selection valve

![Diagram of solvent degassing before the solvent selection valve]

**Figure 13** Solvent degassing before the solvent selection valve

**Pro:** Short flush times (the degasser chamber does not need to be flushed)

**Con:** Potential re-solution of air in the longer tubing from the degasser to the pump, more than one degasser required

Required parts:

- the requisite number of G4225A degasser units (one degasser is for four solvents only)
- Solvent cabinet 1200 Infinity, including all plastic parts (5065-9981) (one is included to the pump)
- Solvent bottle, amber, 1000 mL (9301-6526) or
- Solvent bottle, clear, 1000 mL (9301-6524)
- n x Solvent selection tubing kit, 4 solvents (5067-4601)
System Setup and Installation
Installing the Solvent Selection Part

Degassing after the solvent selection valve

![ Degassing after the solvent selection valve ]

Pro: No risk of re-solution of air, only one degasser required

Con: Considerably longer flushing times because after every solvent change, the degasser chamber (with the G4225A ca. 1.2 mL) needs to be flushed thoroughly, which means with at least five times the volume of the degasser chamber.

Required parts:
- 1x G4225A degasser
- Solvent cabinet 1200 Infinity, including all plastic parts (5065-9981) (one is included to the pump)
- Solvent bottle, amber, 1000 mL (9301-6526) or
- Solvent bottle, clear, 1000 mL (9301-6524)
- n x Solvent selection tubing kit, 4 solvents (5067-4601)
Installing the Solvent Tubing

One solvent selection tubing kit (Solvent selection tubing kit, 4 solvents (5067-4601)) is delivered with all required parts to connect up to four solvent bottles to the 12-Position/13-Port valve (G4235A) on the G1170A External Valve Drive. If you need more solvents, additional kits need to be ordered.

Depending on whether degassing is done before or after solvent selection, there are two possible set-ups for the hydraulic connections, as described below.

Degassing with several degassers before the solvent selection valve:
1  Place the solvent bottles in additional solvent cabinets on top of the degasser.
2  Use the pre-installed bottle head assemblies to connect the bottles with the degasser inlet ports.
3  Cut appropriate lengths of the 2 x 5 m solvent tubing and fit them to the fittings.

NOTE
Use the prefitted bottle head assemblies as examples of how these are fitted together.

4  Attach the PEEK-adapters to the ports of the 12-position/13-port valve and connect the solvent tubing from the outlet port of the degasser to the peripheral ports of the valve.
5  Connect the central port of the 12-position/13-port valve to one port of the pump, or to one port of the optional internal solvent selection valve of the pump (binary pumps only).
Degassing after the solvent selection valve:

The pre-installed tubings need to be replaced with much longer ones that have to be cut to appropriate lengths from the 5 m tubing.

1. Disassemble the bottle head assemblies.
2. Cut appropriate lengths of the 2 x 5 m solvent tubing.
3. Refit the bottle head assemblies with the longer tubings.
4. Connect the tubings with the peripheral ports of the 12-position/13-port valve using the PEEK adapters.
5. Connect the central port of the 12-position/13-port valve with the inlet port of one degasser channel and the corresponding outlet port with one channel of the pump.

In both cases, make the corresponding settings in the software (entering the clustering information, and entering the names of the solvents into the solvent table).
This chapter explains how to configure the system in the control software and how to create methods.
Clustering of Modules in ChemStation using the RC.NET Drivers

During autoconfiguration, if the system detects that there are modules that can be clustered, a dialog box is displayed (Figure 15 on page 56) that allows you to select the modules via check boxes to be included in the cluster. You select the modules for the Column Compartment Cluster and the Pump/Valve Cluster separately.

![Figure 15](image)

**Figure 15** Screen *Agilent LC Modules and Systems Auto Configuration*, Selection of modules to be included in the cluster

To start the clustering, klick one of the available cluster option buttons.
Column Compartment Cluster Configuration (VTC)

When you click **Configure Valve Thermostat Cluster** in the cluster creation dialog box (Figure 15 on page 56), the VTC configuration dialog box is displayed that allows you to configure the column compartment cluster.

Select the topology with the drop-down list and the topology scheme will be shown beneath. Red caution icons indicate, that valves are not defined yet.

**Example 1: Topology 1 VC for long columns**

Topology 1 enables clustering of one valve with up to eight columns. And with two MCT modules it is possible to use up to 8 long columns.

![Figure 16 Screen Valve Thermostat Cluster Post Auto Configuration](image)
First you have to update your module list by adding or removing modules. Use the up/down arrow buttons to move the clustered column compartments up or down in the table. The position in the table should reflect the physical set-up of the system. The sequence you select here is displayed in all column compartment cluster images.

Click **Configure...** (when you add a module, you are automatically asked to configure it after having confirmed your module type) and select your valve version by a drop-down list with a click on **Not installed** (see Figure 17 on page 58).

![Figure 17](image-url)

**Figure 17** Screen **Configure single device**, installing valve versions

If this setting is completed, you have to assign the valve in the topology scheme with a click on the red caution icons or finger icons. A context menu will show available valves. This needs to be repeated for each valve in the topology.

The Plumbing section enables you to specify how the installed columns are connected to the column selection valve, and where they are located in the column compartment cluster. The valve positions are color-coded; the colors are reflected in the Column Assignment diagram (see Figure 24 on page 66).

Colors usages and locations are all specified using drop-down menus in the relevant cells. Column locations are specified by column compartments (**Column Host**) and position (**Location**). Note that if you specify a long column occupying both left and right positions in a column compartment, the temperatures of both heat exchangers are coupled and set to the same temperature. This has implications for any other columns in the same column compartment. Any conflict in the configuration is marked with a red warning sign, and a tooltip gives the reason for the error.
For Plumbing, select the **Color Code, Usage, Column Host**, and **Location** from the drop-down list which appears by clicking on the corresponding table cell.

**NOTE**
With this flexible system, all selectable plumbings are possible. But to keep track of the system, a logical assignment is very helpful. You can see all paths in the topology scheme by clicking on the path number in the plumbing table. Finally, you will have an overview of the set hydraulic connections by clicking **Print Connections**.

**Example 2: Topology 2 V(VC)₂**

With branched topologies, it is possible to increase the number of columns. In topology 2, the simplest form, typically an external root valve (first level) branches between two MCTs (second level).

![Figure 18](image-url) Screen Valve Thermostat Cluster Post Auto Configuration, Configuring Topology 2
When the valves are assigned (see Figure 16 on page 57), in branched topologies a default port of the host valve (level 1) is proposed (indicated by a number left to the valve). This is the port of the valve to the left (level 1 valve), where the valve to the right (level 2 valve) is connected to. In order to change this port (e.g. to achieve a shorter capillary connection), click on the number and select a different port number from the drop-down list (see Figure 19 on page 60).

**NOTE**

The selected number is the valve switching position and not the port (they may be equal).

---

**Figure 19**  Valve switching positions

Topologies 3 and 4 are configured in the same way.
Example 3: Topology 5 V-C-V

This topology uses two bracketing valves: one for inlet and one for outlet. The left valve is the inlet valve in the high pressure flow path, the right one the outlet valve in the low pressure flow path downstream to columns. With this topology TCC-clustering is possible and can only be used with two 8-pos/9-port valves.

![Valve Thermostat Cluster Post Auto Configuration](image)

Figure 20  Screen Valve Thermostat Cluster Post Auto Configuration, Configuring Topology 5
Solvent Delivery Cluster Configuration

When you click **Configure Pump/Valve Cluster** in the cluster creation dialog box (Figure 15 on page 56), the **Pump Valve Cluster Configuration** dialog box is displayed that allows you to configure the solvent delivery cluster (see Figure 21 on page 62).

![Figure 21 Screen Pump Valve Cluster Configuration, Tab Configuration](image)

During autoconfiguration, the dialog box sections contain the pump and valve(s) that were selected in the cluster creation dialog box. To complete the configuration of the solvent delivery cluster, you specify the pump channels the valves are associated with by selecting from a drop-down list in the **Channel Configuration** table. The table lists all available channels, depending on the configured pump:

- **Quaternary pump**: A, B, C, D
- **Binary pump**: A, B
- **Binary pump with internal solvent selection valve**: A1, A2, B1, B2
Solvent configuration

Use the Solvents tab, available in the post-autoconfiguration mode, to specify the solvent for each column. All available channels are listed; the number of available channels depends on the configured pump and the number of valves in the cluster.

In addition to specifying the solvent name and either specifying a compressibility value (G1311B, G7111B) or selecting a solvent definition (G1312B, G4220A/B, G7120A), you can optionally specify other solvent characteristics (pH, viscosity and molarity).

![Screen Pump Valve Cluster Configuration, Tab Solvents](image)

Configure Solvent Type Catalogs opens the Solvent Type Catalogs, which lists all available solvent types.
The solvent name that is reported is automatically concatenated from your entries in the columns **Solvent**, **pH** and **Molarity** (if you enter values for pH and/or molarity) as in the following example:

<table>
<thead>
<tr>
<th>Column</th>
<th>Your entry</th>
</tr>
</thead>
<tbody>
<tr>
<td>Solvent</td>
<td>Phosphate buffer</td>
</tr>
<tr>
<td>pH</td>
<td>4.5</td>
</tr>
<tr>
<td>Molarity</td>
<td>20</td>
</tr>
</tbody>
</table>

The **Solvent Name** automatically generated and used by the system will be: *Phosphatebuffer pH: 4.5 20mM"

**NOTE**
The pH value is used by the Method Scouting Wizard to check for potential incompatibilities of columns and solvents. The viscosity column is for future use.

**Bottle fillings**

Bottle sizes and fillings are managed by the standard bottle filling interface. The system automatically assigns the values to the selected solvents of the external valves according to the valve positions.
Settings for Column Compartments

Columns definition

To specify the columns, select Instrument > Columns. Fill in the columns you regularly use in your lab, see Figure 23 on page 65. This information is required for configuring the column locations shown in Figure 24 on page 66. You should enter at least a Description, the physical dimensions and, if these values are identical for some columns, a serial number to allow correct identification later. If you are using the Method Scouting Wizard, it is important that you set the column void volume correctly using [mL] as units, otherwise flushing and equilibration times will not be calculated correctly.

Alternatively, the total porosity can be entered by selecting [%] as units (e.g. 60 %). In this case the column dimensions in [mm] must be entered as well otherwise the column void volume cannot be calculated.

When you are using the Method Scouting Wizard, it is also advisable to enter a maximum temperature and maximum and minimum pH values. It is not required to enter the Installed value (this entry is needed only for non-method-development systems). See in the User Contributed Libraries on the ChemStation DVD for a tool to import column tables.

Figure 23  Screen Edit Columns, Table of columns which are used for method development experiments

The Installed value is not used in case of a column compartment cluster.

Plumbing... leads you directly to the Column Assignment (see Figure 24 on page 66).
Configuring the System in ChemStation and Creating Methods

Settings

**Plumbing** (see Figure 24 on page 66) enables you to specify how the installed columns are connected to the column selection valve, and where they are located in the Thermostat.

The valve positions are color-coded; the colors are reflected in the **Column Tag Information** and shown in the **Visualization** scheme.

![Column Tag Information](image)

**Figure 24** Screen Column Assignment
The **Column Tag Information** tab shows information about the types of columns used for analysis. With a click on the icons in the **Import** column, you can select the column from a list which can be imported with all parameters (see **Figure 25** on page 67).

**Figure 25**  
Screen Import Column From Column Database
Method setup for Multicolumn Thermostat

After configuration of all columns, select **Instruments > Set Up Column comp. (G7116B)** to setup the parameters for analysis.

![Screen Method of VTC, Setting parameters for the analytical run (MCT)](image)

**Figure 26**  Screen Method of VTC, Setting parameters for the analytical run (MCT)
The user interface allows to set the following parameters:

- **Path/Column**
  The position of the column in the MCT and the corresponding valve position are shown in the graphical representation. Together with the color code, this allows the identification of the flow path.

  The column used for the individual method can be selected in the Method window of the 1290 Infinity II Multicolumn Thermostat. The appropriate column can be selected either by the drop-down menu, which shows all assigned columns, or by just clicking the column with the correct color code in the image of the 1290 Infinity II Multicolumn Thermostat. The current valve position, which automatically connects to the chosen column, is shown. For quick information, the valve position, the color code of the chosen column, and its product number are shown in Agilent ChemStation.

- **Temperature of Selected Zone**
- **Stop time**
- **Post time**
- **Advanced**

  In **Temperature Settings**, a list of the temperature zones is given and the corresponding options for enabling analysis. Selected columns in the schema are indicated in the list with a blue arrow.

  The software recognizes the position of the front door (open or closed) of the MCT. By default, an analysis starts only when the door is closed (recommended); however, when the corresponding check box is marked, the analysis is enabled even with an open door.

- **Timetable**

  If you need to apply temperature gradients during a run, click **Add** and enter the additional time programming of the temperature.
Configuring the solvent table

If an external G4235A solvent selection valve is clustered, solvents can be specified and named by selecting Instrument > More Pump Valve Cluster > Pump Valve Cluster Configuration, see Figure 27 on page 70.

The left column shows the valve position. In the Solvent Name column, you can assign a name to the solvent attached to that valve position. For pumps using calibration tables for the compressibility and elasticity of the solvents (for example the G1312B Binary Pump), you also need to enter the Calibrated Solvent here. The entry for the pH Value is optional, but is recognized in the Method Scouting Wizard to exclude incompatible combinations of solvents and columns.
Actual Volume and Total Volume are set in the Bottle Fillings dialog (also for the solvents attached to the solvent selection valve), see Figure 28 on page 71.
Method setup for solvent delivery cluster

In the pump setup screen, the solvents for an experiment can be selected without the need to switch the solvent selection valve to the appropriate position in an additional screen, see Figure 29 on page 72. You simply select the solvent that you want to use by its name. If you need to enter a calibrated solvent for the pump that is installed in your system, it is taken automatically from the solvent table (see Figure 27 on page 70).

![Figure 29 Screen Method of PumpValveCluster, Selecting a mobile phase attached to the solvent selecting valve](image)

After configuring and setting up the complete system, you can set up the different methods for the different columns, set up the sequence and start it.
This chapter provides information on installation, use and features of the software.
Overview of the Agilent Method Scouting Wizard

The Agilent ChemStation Method Scouting Wizard is a software add-on to the OpenLAB ChemStation that enables you to scout LC parameters like solvent, column, temperature and gradient applying an Agilent Method Development System. The software automatically generated a logical sequence of the different methods including flushing, equilibration and column storage runs.

In this respect, it uses waste and/or available bypass lines intelligently to allow fast flushing procedures. Flushing, equilibration and column storage procedures, and temperature changes are arranged in the workflow such that a minimal number of these steps need to be performed to save valuable time and solvents. In Figure 30 on page 74, a part of a complete sequence is shown as an example of how the different steps are put together.

![Figure 30](image-url)  Different steps during a method scouting campaign as generated by the Agilent ChemStation Method Scouting Wizard

The analysis is performed on column 1 using a solvent combination A/B, followed by post-run storage of column 1 in a special storage solvent D, and finally switching to column 2 using a new solvent combination A/C. The system has a waste line available (see “Specifying and Selecting Gradients” on page 88 and “Settings for System Volumes, Flushing, Equilibration and Column Storage” on page 96).
Features

The Agilent Method Scouting Wizard provides customer benefit in LC method development. For an overview on features of the software, see Table 5 on page 75.

Overview of the Agilent Method Scouting Wizard

Scouting Sequence Optimization

MSW decides on the optimal sequence run order now based on calculating several different run orders with varying combination priorities of solvent, column and temperature changes. These single results, by itself optimal in their run structure, are finally compared to determine the overall optimal sequence with the shortest total run time and best solvent usage under given setup conditions.

Support Intelligent System Emulation Technology (ISET)

MSW supports ISET functionality with solvent screening when using a pump method with enabled emulation mode (ISET).

</table>
Software Compatibility

To take full advantage of InfinityLab LC Method Development Solutions, Agilent Method Scouting Wizard (MSW) software is recommended.

To run MSW A.02.08 with all its features, it is required to have OpenLAB CDS ChemStation Edition C.01.08 installed.

This MSW version is not backwards compatible and cannot be installed on a lower ChemStation revision.

Please be aware, that neither MassHunter nor EZChrom support MSW.

Instrument Driver

The MSW only supports LC RC.Net drivers; the classic driver architecture is NOT supported!

The following minimal LC RC.Net driver is required for revision MSW A.02.08:

- Agilent LC/CE Driver Package A.02.18

**NOTE**

Make sure that driver version A.02.18 is installed:

- Check the installed driver version with your OpenLAB CDS ChemStation Edition C.01.08.
- Upgrade or downgrade if the driver version is different.
Software Installation

Prerequisites

If there is a previous version of the Method Scouting Wizard on your computer, open the Windows Control Panel, select Add or Remove Programs and select to remove the previous version.

1. To install the Agilent Method Scouting Wizard, follow the instructions given in the Install Instructions.pdf located on the Method Scouting Wizard disk.
Defining the Campaign

All methods, the sequence, and the project file that contains all settings of a campaign are saved in a screening-campaign folder. You can create a new campaign or open an existing one. In the latter case, you can choose between overwriting the old one and saving it with a new name. Create a new screening campaign includes naming of the campaign and specifying the path where the campaign is saved. It is recommended to save the campaign in a separate folder, such as Screening. This screen is always the start for the setup of an experiment (see Figure 31 on page 80).

![Method Scouting Wizard](image)

**Figure 31**  Start screen for a campaign

**NOTE**

You can open a screening campaign from the previous revision of Method Scouting Wizard. If the current instrument configuration does not match the instrument configuration of the old campaign, the campaign will be adjusted accordingly. When you save the campaign, it is automatically converted into the format of the current revision.
You can also view an existing screening campaign; all the information for the campaign is displayed in the sequence of screens, but you cannot make any modifications, and all buttons that allow modification are hidden. The compatibility of the current instrument configuration is not checked, and the base method is not required to be available. This allows you to review the content of any existing campaign without modifying it.
Define Screening Campaign Base

For a method scouting campaign, a base method needs to be set up (you do this as usual in the ChemStation - it is recommended to use Edit Entire Method). All parameters that are not changed are taken from this base method. These are typically the detector settings, autosampler settings, pump settings that are not altered, and data processing parameters (see Figure 32 on page 83).

In addition to selecting the base method, you also need to specify the scope of the screening campaign. That means the combinations of column screening, solvent screening, gradient screening and temperature screening that you would like to perform. Here, you specify the dimensions of the method scouting campaign; in the next screens, the ranges of the selected dimensions are specified.

NOTE

With a quaternary pump ambiguities could occur if "solvent screening" is selected and the gradient would be taken form the base method during solvent screening. To prevent this if no gradient screening is selected, the "gradient screening" will be checked automatically. If no gradient screening is demanded by the user only one gradient has to be defined in the later gradient screening page.
Screen for defining the campaign range and selection of the master method
Selecting the Columns

In this screen, you select the columns to be evaluated (see Figure 33 on page 84). You can select only the columns that are installed in the system and have been specified previously in the Configuring Columns user interface screen under Instruments. The installed columns as defined will be shown in the Method Scouting Wizard; important variables such as the position, the specified void volume, the maximum temperature and pH-value are shown, but are not editable. Column properties are read from the Columns table of the ChemStation. You select the columns you want to use in the method scouting campaign by checking the Use check boxes.

Figure 33  Selection of columns

The two check boxes below the table allow you to scale flow rates and gradients for columns with different dimensions.
**Scale flow for column with largest diameter** ensures that the velocity of the eluent is maintained irrespective of the diameter of the column. Flow rates of narrower columns are reduced relative to those of wider columns in the ratio of the squares of the column internal diameters.

**Scale (gradient) run times for longest column** ensures that the full gradient will run on all columns, irrespective of their length. All gradient time points, the run time and the posttime for shorter columns are reduced relative to those of longer columns in the ratio of the column lengths.

If you do not select column screening as a dimension of the method scouting campaign, the column specified in the base method is used.
Selecting the Solvents

If solvent screening is selected, the solvents to be varied are specified in the following screen (see Figure 34 on page 86). The Method Scouting Wizard automatically detects the system configuration and shows the appropriate screen. For a binary pump without any additional solvent selection valves, no solvent choices are available. If an additional internal solvent selection valve is installed, the solvents to be used can be selected. If an additional external G4235A solvent selection valve is installed, all solvents that are available and specified in the solvent table are shown as choices for the corresponding channel where the valve is installed. You mark the corresponding check boxes of the solvents that are used to create binary gradients.

Fill in the ratio of channel A to channel B (in %).

Figure 34  Selecting the solvent with a binary pump

If a quaternary pump is installed, the Set Up Solvent Screening screen looks slightly different, see Figure 35 on page 87. Again, the position of an optionally installed external solvent selection valve is detected. Additionally, you choose
to create binary, ternary or quaternary gradients. Besides, for quaternary gradients that do not allow further choices you specify here which variations should be created, that is for a binary gradient on a system with an external solvent selection valve attached to channel A, for example, combinations of those solvents on A versus the B-, C- and D-channel (A_01-B, A_01-C, A_01-D, A_02-B, A_02-C, A_02-D, etc). Other combinations might be solvents on the A-channel as well as the B-channel versus the C- and D-channel (A_01-C, A_01-D, A_02-C, A_02-D, B-C, B-D, etc).

The number of selected solvent combinations and the maximum possible number of combinations with the given system are indicated at the bottom of this screen.

Figure 35  Set up solvents screening using a quaternary pump, a setup for a binary gradient of channel A (with an attached external solvent selection valve) versus the channels B, C and D is shown.

If no Pump Valve Cluster is set-up and you use a single pump, the entry of the pH value is not supported at the driver level. In this case, the Agilent ChemStation Method Scouting Wizard allows you to enter the pH-values of the solvents at this point.
Specifying and Selecting Gradients

If the gradient is also to be varied, the following screen is displayed, where you can specify gradients, their initial composition, run time, post-time and the flow rate to be used. You have the possibility to enter the gradients based on a table (time vs. percentage of solvent, see Figure 36 on page 88) in the Table tab or graphically (see Figure 37 on page 89) in the Graph tab. With the graphical tool, you can set gridlines and specify that the cursor snaps onto the gridlines, with selectable snapping ranges. Finally, you can also overlay the selected gradients in the Overlay tab, see Figure 38 on page 89.

![Figure 36](attachment:image.png)  Defining and selecting different gradients - gradient table
The Agilent ChemStation Method Scouting Wizard

Specifying and Selecting Gradients

Figure 37  Defining and selecting different gradients – graphical interface

Figure 38  Defining and selecting different gradients – overlay interface
It is extremely important to set the initial composition correctly. This is the composition that the pump generates after the method is loaded but the injection has not yet occurred, and the composition that is used after the run time (data acquisition) has elapsed and until the next method is loaded (for example, during the post-time or system overhead time). If you do not explicitly change the initial composition the one from the base method is used.

*The initial composition determines the settings for a flushing or equilibration method that is executed immediately before the gradient method is applied to a sample, or a subsequent column storage method that does not use a dedicated storage solvent.*

A simple linear gradient consists of one line in the table – the final composition that has to be reached. If the time value of the final composition is lower than the run time, the final composition is held until the run time is reached. If you have set a post-time, the initial composition is applied from the “run time” until the “post-time” (see Figure 39 on page 90). To correctly specify gradients, you also need to consider how the Method Scouting Wizard applies the Equilibration procedures (see “Settings for System Volumes, Flushing, Equilibration and Column Storage” on page 96). Take care when setting time values at 0 min or close to 0 min; unless this value matches the initial composition, you will have a situation with an improperly equilibrated column and maybe non-reproducible results, see Figure 41 on page 91).

**NOTE**
Be sure to use either the post-time or to have a suitable time point set in your gradient method to ensure column equilibration after repeated use of the analytical method (e.g. multiple injections or multiple samples) See “Settings for System Volumes, Flushing, Equilibration and Column Storage” on page 96.

---

**Figure 39** Typical gradient setting with post-time. Equilibration occurs during the post-time without data acquisition during that time.
Figure 40  Typical gradient setting without post-time but an added equilibration period in the gradient table. Data acquisition occurs during the equilibration phase of the column.

Figure 41  Avoid composition settings at 0 min or close to 0 minutes in the gradient table that do not match the composition of the initial composition as this leads to improper equilibration.

**NOTE**

The pump flow rates apply at least for the methods for columns with the largest internal diameter. If the **Scale flow for column with largest diameter** check box is marked on the **Set up column screening** page, then the flow rates will be adjusted relative to the squares of the column IDs.

The gradient times apply at least for the methods for the longest columns. If the **Scale (gradient) run times for largest column** check box is marked on the **Set up column screening** page, then the gradient times will be adjusted relative to the column lengths.
Defining and Selecting the Temperatures

If you also selected temperature screening, you can enter the temperatures you want to test (see Figure 42 on page 93). You can enter all values that are available for the given system.

**NOTE**

If you are using a mixed system containing a G1316C and a G1316A column compartment, the maximum temperature is defined by the G1316A (80 °C instead of 100 °C). The lowest temperature that can be entered is -5 °C.

The G1316-series column compartments are able to cool to 10 °C below ambient, but since the ambient temperature can change during the course of the analysis series, you should consider having some safety margin. If your lab has a rather high ambient temperature, you might want to set the lowest screening temperature to approximately 20 – 25 °C. If this temperature cannot be reached, the column compartments stays in a not-ready state because the Method Scouting Wizard enforces the analysis to be enabled only when the column compartment has reached the set-point in the allowed range as specified in the base method (**Set Up Column Thermostat Cluster > Enable Analysis**). For flushing or column storage methods, the method starts without reaching the set point.
The Agilent ChemStation Method Scouting Wizard
Defining and Selecting the Temperatures

Figure 42  Temperature screening window
Review the Selected Methods

This screen shows you an overview of all combinations of columns, solvents, gradients and temperatures (see Figure 43 on page 95). Additionally, two check boxes at the bottom allow you to automatically deselect incompatible combinations of columns with solvent-pH and temperatures. This option requires that the values for **max temp.** and **max/min pH** are set for the columns in the ChemStation column database, and that the solvent pH is set correctly in the solvent table of the pump if an external G4235A solvent selection valve is clustered to the system or in the solvent screening interface. The allowed pH range and temperature of the column is shown in the table and marked either with a green or red color to indicate compatible and incompatible values. If the maximum temperature value for a column is not available, you cannot exclude columns on the basis of temperature; if the pH values for a column are not available, you cannot exclude columns on the basis of pH.

By clearing the Use check boxes in the left column of the table, you can eliminate unwanted combinations of the full matrix. This is very useful, because it allows you to save and re-use such special scouting campaigns with other samples.

The total number of methods is shown at the bottom, and gives a quick overview on the complexity of the specified scouting campaign. Detailed information is available at the end after flushing, column storage and equilibration procedures have been specified and added to the campaign.
Figure 43  Review and select analytical runs to be performed
5 The Agilent ChemStation Method Scouting Wizard
Settings for System Volumes, Flushing, Equilibration and Column Storage

Settings for System Volumes, Flushing, Equilibration and Column Storage

This important screen allows you to specify the following settings (see Figure 44 on page 97 and Figure 46 on page 104):

- how solvent lines are flushed after a solvent change has occurred
- how a column is taken care of after it has been used
- how columns are equilibrated
- how the data files created during any of the above procedures are handled

**NOTE**

If the number of sequence lines required for analytical runs as specified by the campaign plus additional blank runs for flushing, column care and equilibration exceeds 1999, a warning is displayed, and you cannot proceed until either the range or dimensions of the screening campaign is reduced. This can be accomplished, for example, by deselecting a dimension such as temperature screening, or reducing the range of a dimension such as fewer gradients or temperatures.

Alternatively, but usually not recommended, you can also deselect flushing, column storage or column equilibration. This takes only one sample into account. If you plan to have more than one sample, you might get another warning during sample set up and need to further reduce the number of sequence entries.

**Defining System Volumes**

First, the volumes of the system that have to be flushed with solvents have to be defined (see Figure 44 on page 97). These settings have to be only entered once and will be stored for following screening campaigns as user defined settings, but they can be altered any time. If an external solvent selection valve is connected to a solvent channel of the pump the position of the degasser has to be selected. Two choices are available - before the solvent selection valve or after the solvent selection valve. In the later case it is necessary that the volume of the degasser chamber will be flushed. For the G1322A degasser, this volume can be significant.
NOTE

If two external solvent selection valves are configured in the system, only degassing either before or after the external solvent selection valves is supported. A configuration with one valve before the degasser and one after it is not supported.

Depending on the availability of an external solvent selection system and the selected position of the degasser, different system diagrams will be shown and different entries have to be made. Move with the mouse over the entry boxes and the corresponding volumes in the system diagram will be highlighted.

Figure 44  Setting of the volumes in the system
The following volumes are required:

- volume from degasser to mixing point of the pump (excluding the degasser chamber) - this volume will be flushed with 100 % of the corresponding solvent

- volume from solvent selection valve to degasser (including the degasser chamber) – this volume can be flushed with 100 % of the corresponding solvent

- volume from the mixing point of the pump to the column inlet - this volume will be flushed with the composition of the following analytical method

Table 6 on page 98 and Table 7 on page 99 gives you some guidelines for the volumes of different parts of a system.

**Table 6**  Typical internal volumes of parts that need to be flushed for a solvent change (for pumps)

</tbody>
</table>

**NOTE**

Sampler: The seat volume has to be added as configured by the customer.
Example:

Degasser after solvent selection valve, system with a binary pump G7120A / 100 μL mixer and the G7167B autosampler with 100 μL Syringe:

Volume from SSV to degasser, incl. degasser:

Ca. 30 cm tubing 0.54 mL
Built-in degaasing unit 1.5 mL

2.04 mL

Volume from degasser to mixer:

20 cm tubing 0.36 mL
Pump head 0.06 mL

0.42 mL

Volume from mixer to column, incl. mixer:

Mixer 0.10 mL
Capillaries ca. 1.2 m 0.12 ID 0.013 mL
Autosampler 0.0615 mL

0.1745 mL

In case more than one solvent line needs to be flushed, for example at initial solvent line flush at the very beginning of a campaign, the pump will be set to a composition that reflects the volume ratios of the different channels (e.g. high percentage for a solvent that is delivered through an external solvent selection valve and a degasser after the SSV and low percentage for the remaining solvents that are directly attached to the degasser).

The void volume is usually taken from the column data base. In few special cases it can be necessary to enter the void volume of the column as well.
Flushing Conditions

If you have included solvent screening, or you want to store your columns with a storage solvent at the end of their usage, solvents have to be exchanged in the system. It is highly recommended not to deselect the flushing option, as this can lead to non-reproducible results.

However it might be appropriate to deselect this option, as for example in the following cases:

- The volumes to be flushed are very low, or
- high flow rates and equilibration conditions cover the times needed to flush the solvent delivery system.

First, it is necessary to select the flushing solvent (see Figure 45 on page 102). Usually, this is the solvent of the next method, but in some cases, it might be necessary to flush the system first with a neutral solvent followed by the solvent of the next method. Cases that require an intermediate neutral solvent might be immiscible solvents or any solvent combinations that might cause precipitation of buffers. If you fear such problems, you can select one of the available solvent from your system, and the complete system (including the column) is flushed first with this solvent and then with the solvent of the following analytical run or a solvent that was selected for a column care procedure (see “Column Storage Procedures” on page 106).

**NOTE**

Note that additional flushing with a neutral solvent doubles the required flushing time.
The settings for the flushing conditions depend on the availability of a waste and/or bypass line in the system. With a waste line, a much higher flow can be applied giving reduced flush time.

If only a bypass line is available, a lower flow rate as with a waste line might be considered, depending on the detector in use. For example, the backpressure generated at high flow rates by the flow cell might be too high for an FLD-detector, and some detectors such as mass spectrometers or ELSD detectors typically have maximum allowed flow rates in the range of 1 – 2 mL/min.

If no waste or bypass line is available the flow needs to go through the column. You must set an appropriate flow rate, taking into account different viscosities and possible immiscibility of the new solvent with the solvent residing in the column.

Finally, the number of flush volumes (n) needs to be entered. The calculated flush time is (n) times the flush volume divided by the flow rate. A value of at least 5 is advisable to achieve a thorough flushing.

If flushing is selected, the solvent lines used in the first analysis are flushed at the beginning of a sequence generated by the Agilent Method Scouting Wizard to ensure proper starting conditions.
Column Equilibration Procedure

If equilibration is selected, a column is treated with the conditions of the following analytical run for the specified time. The equilibration time can be set to a fixed value or can be calculated depending on the column void volumes. The column volume used for some of the calculations is taken from the column data base in ChemStation, and correct settings are assumed. To calculate the void volume of a column use the following equation:

\[ V_m = \pi \left( \frac{d_c}{2} \right)^2 \cdot L_c \cdot \frac{\varepsilon}{1000} \]

where

- \( V_m \): column volume [mL]
- \( d_c \): internal diameter [mm]
- \( L_c \): column length in [mm]
- \( \varepsilon \): total porosity

Typically, the total porosity, which is the fraction of the column that is not taken up by the stationary phase and accessible to the mobile phase, is in the range of 0.6 – 0.8; for example, an Agilent Zorbax reversed phase column has a total porosity of ca. 0.6. In this case, a minimum of 5 column void volumes should be exchanged to ensure a proper equilibration, but much higher values might be appropriate, depending on the type of columns used.

NOTE

The value set here is used for all columns. If a certain column needs significantly longer equilibration times, you could deliberately set the value in the column data base to a higher value than the physical value to achieve a longer flushing time for this column.

NOTE

The use of the column equilibration procedure is highly recommended.
If the equilibration time has been specified directly in minutes, and not calculated from the column void volume, and time scaling has been defined on the **Set up column screening** page, the respective column length ratio, $r$, is applied to scale the time as given in the user interface.

The equilibration time specified here refers to columns without extended equilibration factor.

The actual equilibration time is a multiple of the time specified here and the column equilibration factor. The actual equilibration time is displayed in the Sequence tab on the **Summary** page.

The equilibration factor $f_e$ applies to the equilibration time $t_e$ only. If a flush tubing volume flow time $t_{flush}$ has been added to the equilibration time $t_e$, the extended equilibration time $t_{ext}$ computes to:

$$ t_{ext} = f_e \cdot t_e + t_{flush} $$
When the column length ratio, $r$, is also applied, the equation becomes:

$$t_{\text{ext}} = r \cdot t_e \cdot t_e + t_{\text{flush}}$$

If column equilibration is not selected, it is recommended that the gradients used in the screening campaign contain an adequate equilibration time, and that the sequence starts with a blank sample. Otherwise, the first run will not have reproducible results. Also, if multiple injections are planned with the same method, either the method must contain a post-time or the gradient must include a programmed time for equilibration.

**Single use of an analytical method**

![Diagram](image1.png)

**Multiple use of an analytical method**

![Diagram](image2.png)

*Figure 47* Top: an analytical method is used only once, then new conditions are applied. The Equilibration procedure ensures proper column equilibration under the new conditions. Bottom: multiple injections or multiple samples are planned. Since the Equilibration procedure is applied only after a change of column, solvents, temperatures or gradient, the method must contain a post-time (or the gradient must include a programmed equilibration period) to ensure proper equilibration in-between the multiple analysis.
Column Storage Procedures

After a column has been used in an analysis, it might be advisable to flush the column with another solvent than the one used for the analysis. A typical example might be after analysis with high buffer concentrations, see Figure 48 on page 106. Different choices of flush solvents are available:

- the starting conditions of the current method, which might be of use if the gradient ends with a high concentration of organic solvent, for example,
- an additional care solvent provided on a separate channel of the solvent delivery system, which is probably the regular case.

**NOTE**
The flushing option should not be deselected.

You can make different settings for the flow rates and the flush times to ensure that a proper solvent exchange inside the column has occurred.

![Figure 48 Settings for column storage conditions](image)
If an extra column storage solvent is used and the flow has been defined directly, and not by the injection/base method, and flow scaling has been defined on the Set up column screening page, the respective column squared-diameter ratio is applied to scale the flow as given in the user interface.

If the time has been specified directly in minutes, and not by column void volume, and time scaling has been defined on the Set up column screening page, the respective column length ratio, r, is applied to scale the time as given in the user interface.

The column storage time as specified here refers to columns without extended storage factor.

The actual column storage time is a multiple of the time as specified on this screen and the column storage factor as specified on the Set up column screening page. The actual column storage time is displayed in the Sequence tab on the Summary page.

The equilibration factor \( f_e \) applies to the column storage time \( t_{cs} \) only. If a flush tubing volume flow time \( t_{flush} \) has been added to the column storage time \( t_{cs} \), then the extended column storage time \( t_{ext} \) computes to:

\[
t_{ext} = f_e * t_{cs} + t_{flush}
\]

When the column length ratio, \( r \), is also applied, the equation becomes:

\[
t_{ext} = r * f_e * t_{cs} + t_{flush}
\]

**Blank-Run Data File Handling**

When this check box is marked, data files generated during flushing, column care or column equilibration runs are deleted automatically. The deletion of these data files is recommended in order to keep the amount of data generated low, but the files might be helpful for problem solving (for example, if compounds are eluted after the end of the analytical run because of improper gradient conditions).
Setting Up the Samples

The samples to be analyzed under the different method conditions are specified in this screen (see Figure 49 on page 109). At the top, you specify the total volume [μL] of a single vial (or well of a microtiter plate).

**NOTE** Only one sort of sample vial must be used.

In the central table, you enter a sample name, select the vial-positions in the graphical representation of the autosampler plates, and specify the individual injection volume and the number of injections per sample and number of repetitions. The total injection volume per sample and condition is calculated (repetitions x injection volume), the total sample volume for the campaign is also calculated (scouting conditions x repetitions x injection volume), and finally the number of required vials is calculated (scouting conditions x repetitions x injection volume / volume of a single vial).

**NOTE** For the number of required vials a safety margin of 10% of the required volume is taken into account.

If either the specified vial positions do not match the amount of vials required, or the vial positions of different samples overlap, a warning is displayed, and you cannot proceed until the faulty condition is cleared. You might also get a warning if the total number of sequence lines including all flushing, column storage and column equilibration methods exceeds 1999 lines.

More sample lines can be added by clicking on the Add button.
Figure 49  Set up the samples
Summary

The last screen of the wizard gives you detailed information on the specified method scouting campaign (see Figure 50 on page 111).

The **Description** tab gives general information:
- number of columns, solvents, gradients and temperatures
- name and path of the selected base method
- column storage and equilibration as well as flushing procedure
- sample names and required total sample volumes
- name and path of the sequence created

The **Sequence** tab shows details of the sequence that will be created:
- the complete sequence is shown including all flush, equilibration and column care lines (these are color coded)
- net run time (calculated without system overhead times)
- estimated run time (calculated with a general overhead factor plus a temperature-dependent factor that takes heating and cooling periods into account)
- number of equilibration, column storage and flush sequence lines
- number of column and solvent changes

The **Solvent Usage** tab gives an estimate of the required solvent volumes based on the type of solvent, the estimated run time for the specific solvent and the flow rate of the different methods using the specific solvent.

All estimated solvent volume is summed to give a total waste volume, which is shown in the last row of the table. If your pump supports a waste bottle and your system is online, the computed waste volume is compared with the waste bottle capacity and is color-coded accordingly.

When you click the **Finish** button, the sequence is automatically set up according to the inputs given in the previous screens.
When you have completed the campaign set up, you can load and start the sequence. Open the **Sequence** menu, select **Load Sequence** and browse to the specified path for the campaigns. Highlight the appropriate campaign and press **OK**. The campaign is now loaded as a standard ChemStation sequence. You can specify the data directory (for example, as sub-directory in the campaign directory) by opening the **Sequence** menu and selecting **Sequence Parameter**; data-file naming conventions and sequence shutdown parameters can also be specified.

**NOTE**

To avoid negative effects on the results (for example caused by improper flushing or equilibration), take the utmost care when making changes to the sequence (for example, deleting sequence lines). It is advisable to make such changes in the Method Scouting Wizard.
The Method Scouting Wizard automatically enters a detailed sample information field giving information about the column, the solvent combination, the gradient and the temperature used for the specific data file. All other standard report fields for sample information, method details etc. are available as usual.

For a fast data evaluation Method Scouting Wizard comes with interactive reporting including the easy method filter. This filter (see Figure 51 on page 112) allows you to set your criteria like number of peaks, minimum resolution and minimum symmetry. After refreshing, the report only contains the methods which fits to your criteria. Moreover the report contains two bubble plots for easy comparison (e.g. the runtime vs. the resolution) of the remaining methods.

Figure 51  Easy Method Filter
For even more advanced and automated method optimization based on chromatographic data and considering aspects of quality by design (QbD), Agilent has partnered with:

Appendix

General Safety Information

General Safety Information

The following general safety precautions must be observed during all phases of operation, service, and repair of this instrument. Failure to comply with these precautions or with specific warnings elsewhere in this manual violates safety standards of design, manufacture, and intended use of the instrument. Agilent Technologies assumes no liability for the customer’s failure to comply with these requirements.

**WARNING**

Ensure the proper usage of the equipment.
The protection provided by the equipment may be impaired.

⇒ The operator of this instrument is advised to use the equipment in a manner as specified in this manual.

Safety Standards

This is a Safety Class I instrument (provided with terminal for protective earthing) and has been manufactured and tested according to international safety standards.

General

Do not use this product in any manner not specified by the manufacturer. The protective features of this product may be impaired if it is used in a manner not specified in the operation instructions.
Before Applying Power

**WARNING**
Wrong voltage range, frequency or cabling  
Personal injury or damage to the instrument

➔ Verify that the voltage range and frequency of your power distribution matches to the power specification of the individual instrument.

➔ Never use cables other than the ones supplied by Agilent Technologies to ensure proper functionality and compliance with safety or EMC regulations.

➔ Make all connections to the unit before applying power.

---

**NOTE**
Note the instrument’s external markings described under “Safety Symbols” on page 122.

---

Ground the Instrument

**WARNING**
Missing electrical ground  
Electrical shock

➔ If your product is provided with a grounding type power plug, the instrument chassis and cover must be connected to an electrical ground to minimize shock hazard.

➔ The ground pin must be firmly connected to an electrical ground (safety ground) terminal at the power outlet. Any interruption of the protective (grounding) conductor or disconnection of the protective earth terminal will cause a potential shock hazard that could result in personal injury.
Do Not Operate in an Explosive Atmosphere

**WARNING**
Presence of flammable gases or fumes  
Explosion hazard

➔ Do not operate the instrument in the presence of flammable gases or fumes.

Do Not Remove the Instrument Cover

**WARNING**  
Instrument covers removed  
Electrical shock

➔ Do Not Remove the Instrument Cover

➔ Only Agilent authorized personnel are allowed to remove instrument covers. Always disconnect the power cables and any external circuits before removing the instrument cover.

Do Not Modify the Instrument

Do not install substitute parts or perform any unauthorized modification to the product. Return the product to an Agilent Sales and Service Office for service and repair to ensure that safety features are maintained.

In Case of Damage

**WARNING**  
Damage to the module  
Personal injury (for example electrical shock, intoxication)

➔ Instruments that appear damaged or defective should be made inoperative and secured against unintended operation until they can be repaired by qualified service personnel.
Solvents

**WARNING**

Toxic, flammable and hazardous solvents, samples and reagents

The handling of solvents, samples and reagents can hold health and safety risks.

➔ When working with these substances observe appropriate safety procedures (for example by wearing goggles, safety gloves and protective clothing) as described in the material handling and safety data sheet supplied by the vendor, and follow good laboratory practice.

➔ Do not use solvents with an auto-ignition temperature below 200 °C (392 °F). Do not use solvents with a boiling point below 56 °C (133 °F).

➔ Avoid high vapor concentrations. Always keep the temperature in the sample compartment at least 25 K below the boiling point of the solvent used.

➔ Do not operate the instrument in an explosive atmosphere.

➔ Reduce the volume of substances to the minimum required for the analysis.

➔ Never exceed the maximum permissible volume of solvents (8 L) in the solvent cabinet. Do not use bottles that exceed the maximum permissible volume as specified in the usage guideline for solvent cabinet.

➔ Ground the waste container.

➔ Regularly check the filling level of the waste container. The residual free volume in the waste container must be large enough to collect the waste liquid.

➔ To achieve maximal safety, regularly check the tubing for correct installation.

**NOTE**

For details, see the usage guideline for the solvent cabinet. A printed copy of the guideline has been shipped with the solvent cabinet, electronic copies are available in the Agilent Information Center or via the Internet.
## Safety Symbols

</tbody>
</table>
Magnetic field
Magnets produce a far-reaching, strong magnetic field. They could damage TVs and laptops, computer hard drives, credit and ATM cards, data storage media, mechanical watches, hearing aids and speakers. Keep magnets at least 25 mm away from devices and objects that could be damaged by strong magnetic fields.

Indicates a pinching or crushing hazard

Indicates a piercing or cutting hazard.

A WARNING
alerts you to situations that could cause physical injury or death.

➔ Do not proceed beyond a warning until you have fully understood and met the indicated conditions.

A CAUTION
alerts you to situations that could cause loss of data, or damage of equipment.

➔ Do not proceed beyond a caution until you have fully understood and met the indicated conditions.

In This Book

This manual contains information on the InfinityLab LC Method Development Solutions. The manual describes the following:

- Introduction,
- System setup and installation,
- Configuration of the system using ChemStation,
- Information on the Method Scouting Wizard,
- Method development strategies.
